

Getting Out the Vote: Do Workers Support Firms' Political Goals?*

Abstract

Firms often face political challenges. Where can they turn for support? Corporate political activity (CPA) research has examined external constituencies, but has largely overlooked firms' own employees. To assess whether workers mobilize to support firms' strategic aims, I test whether employees vote at higher rates when firm-relevant strategic issues are on the ballot. Leveraging novel individual-level data on millions of workers, I find that workers turn out to vote at significantly higher rates (1.86 p.p.) in U.S. elections where their employer contributes to a state or local ballot measure campaign. The magnitude of workers' mobilization depends upon the nature of the political issue. For ballot questions with high material stakes for workers, workers' turnout is 6.11 p.p. higher, nearly as large an increase as repeated outreach by political campaigns in crucial swing states. By contrast, ballot measures with low or absent material stakes are associated with small turnout differences (1.18 p.p.). Additionally, in elections for U.S. House—where voters vote to elect partisan representatives rather than directly on proposed policies—firm support for candidates is not associated with higher worker turnout. These results provide the first empirical evidence that workers can serve as a valuable internal constituency to politically support firm strategy, but also suggest that workers' support is limited to cases where firms and employees share common aims.

Keywords: employee mobilization, constituency building, corporate political activity, nonmarket strategy, Revelio

This work was supported by the U.S. National Science Foundation's Learning the Earth with Artificial Intelligence and Physics (LEAP) Science and Technology Center (STC) (grant #2019625), as well as the Institute for Humane Studies. This research used the Savio computational cluster resource provided by the Berkeley Research Computing program at the University of California, Berkeley (supported by the UC Berkeley Chancellor, Vice Chancellor for Research, and Chief Information Officer), as well as Bridges-2 at the Pittsburgh Supercomputing Center through allocation SOC260009 from the Advanced Cyberinfrastructure Coordination Ecosystem: Services & Support (ACCESS) program, which is supported by U.S. National Science Foundation grants #2138259, #2138286, #2138307, #2137603, and #2138296. The Politics at Work project (politicsatwork.org) received financial support from the University of Maryland and the University of Michigan. I additionally thank David Broockman and Hunter Rendleman for support with this study. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the U.S. National Science Foundation or any other supporting organization.

1 Introduction

Firms compete across both market and nonmarket domains. Accordingly, a firm's ability to shape institutional "rules of the game" is a key component of firm strategy (Baron 1995a,b). Research into corporate political activity (CPA) describes how firms seek to influence political outcomes for their own strategic advantage. Much of this research focuses on lower-profile strategies firms use to quietly build influence with policymakers, such as lobbying and campaign finance (Hillman and Hitt 1999; Hillman et al. 2004; Katic and Hillman 2023; Wei et al. 2023). However, not all policy areas are amenable to quiet resolution via lower-salience channels that fly below the level of public awareness (Culpepper 2010). Some strategic issues are contested via high-profile public political fights that require companies to make their case directly to citizens. For example, social movements may launch public advocacy campaigns against firms or industries, or dominant incumbents may seek public support to exclude new competition or ban disruptive technologies (McDonnell and King 2013; King and Soule 2007; Yue et al. 2013).

A number of recent examples illustrate how firms rely upon public support to advance strategic goals or protect against threats. In 2018, Oklahoma voters were asked whether to allow Walmart to operate in-store eye clinics to perform exams and sell glasses. While Walmart argued their clinics would lower prices, existing optometrists argued that doctors at Walmart-owned clinics would face pressure to lower medical standards, putting patients at risk. Similarly, in 2022, Colorado voters were asked whether to loosen state laws on wine sales and home alcohol delivery, pitting incumbent liquor stores against grocery stores, convenience stores, and food delivery apps. And in 2024, Missouri voters were asked whether to allow online sports gambling, a measure opposed by the state's existing riverboat casino operators.

All three elections were preceded by political campaigns fought with corporate dollars. In Oklahoma, Walmart spent \$4.6 million against \$3 million from the state's optometrists and opticians. In Colorado, Albertsons, Kroger, 7-Eleven, DoorDash, and Instacart spent over \$14 million, while local liquor stores spent nearly \$1 million in opposition. And Missouri's fight over online sports betting involved \$45 million spent by online betting platforms DraftKings and FanDuel, versus \$9 million from the state's existing riverboat casino operators. In the end, all three measures were decided by narrow margins. Oklahomans defeated Walmart by only 5,000 votes, roughly 0.5 percentage points (p.p.). Coloradans

backed wine sales in chain retailers by 3.5 p.p., but rejected home alcohol delivery by 2.3 p.p. Finally, Missourians approved sports gambling by less than 3,000 votes, an extremely tight margin of only 0.1 p.p. (Ballotpedia 2025).

As the examples above illustrate, firms require public support to advance strategic goals and protect against external threats. While elections provide an especially vivid example, public support can be strategically useful across a range of different institutional settings. Because policymakers are ultimately accountable to the public, firms can point to public support to convince policymakers why they should enact their preferred outcomes (Kollman 1998). Members of the public can also serve as effective advocates or lobbyists by engaging in behaviors such as calling lawmakers' offices, writing comments to regulators, or speaking during public planning meetings (Lord 2000; Wen et al. 2024). Firms' public support may also be translated into more subtle and less visible types of structural power that can complement or even substitute for other channels of political influence (Bombardini and Trebbi 2011; Lindblom 1977; Kollman 1998).

However, the most direct avenue for public support to help firms—and the one I focus on here—is through voting. Many public policy outcomes with high relevance for firm strategy are decided at the ballot box, thus requiring the support of voters. Where can firms look for this type of political support? Existing research within corporate political activity has focused on firms' efforts to build external constituencies through public relations campaigns targeting the public (Walker 2012, 2014) and/or consumers (Wen et al. 2024) as well as partnerships with social activist groups and non-governmental organizations (Dorobantu et al. 2017; Gama and Gatignon 2025; Odziemkowska and Zhu 2025). While constituency building efforts can expand a firm's reach, studies have highlighted the difficulty and risks of relying upon external partnerships and public outreach (Odzienkowska 2022; Murphy et al. 2024). By contrast, I focus on a constituency that is far more likely to be naturally aligned with and sympathetic towards firms' political goals: their own employees (Keim and Zeithaml 1986; Lord 2000). In races decided by hundreds or thousands of votes—such as those in Oklahoma, Colorado, and Missouri—employees themselves could potentially deliver the winning margin. Even where employees themselves may not constitute a significant enough voting bloc, employees can also mobilize or persuade others within their networks of family and friends (Hurst et al. 2025; Nickerson 2008).

But will employees actually politically mobilize and perform costly actions such as voting in support of firms' strategic goals? Existing research into employees' political support for their employer has

been limited to elites, such as CEOs (Barber IV and Blake 2026) or wealthy and politically engaged executives who make political donations (Li 2018; Richter and Werner 2017; Stuckatz 2022a; Stuckatz et al. 2025; Teso 2025). By contrast, no research evaluates the potential for rank and file employees to also serve as a base of political support. Whereas executive and senior corporate officials may be part of formulating firms' political strategy—and also potentially likely share a greater stake in the firms' future—it is less clear that rank and file employees will be similarly motivated to mobilize in support of their firm. Although we know that politics are often discussed at work (Hurst and Lee 2025; Mutz and Mondak 2006; Selenko et al. 2025), including explicit appeals for workers to vote in certain ways or support particular policies (Avenancio-León et al. 2026; Frye et al. 2025; Hertel-Fernandez 2017, 2018; Stuckatz et al. 2025), there is little evidence as to whether rank and file employees actually mobilize to take costly political actions in support of firms' strategic aims.¹

To establish whether employees mobilize in support of firms' strategic goals, I focus on workers' turnout in elections and measure whether workers turn out to vote at higher rates in elections which are strategically important for their employer. To do this, I assemble new large-scale data covering thousands of firms and millions of employees. This includes campaign finance data spanning federal, state, and local elections, as well as linked administrative data that link tens of millions of workers with official administrative records of their voting turnout history (see Frake et al. 2026; Kagan et al. 2026).

I first focus on ballot questions which are held in U.S. states and local jurisdictions. I gather data on all state ballot questions held between 2016 and 2024, as well as selected local elections in states with publicly accessible campaign finance data. I then collect data on corporate spending in these elections to identify elections where firms donated to political campaigns to advance their strategic priorities, and identify nearly 800,000 workers at 1,617 politically active firms across 303 ballot questions in 39 states. Using stacked difference-in-differences (Cengiz et al. 2019; Wing et al. 2024) to compare workers at politically active firms with matched control workers, I find that workers turn out at 1.86 percentage points higher rates in elections in which their employers are politically active. The content of ballot questions also significantly moderates the size of the estimated difference in worker turnout. Higher turnout is concentrated in ballot questions with large material implications for workers themselves: measures with high material stakes that directly implicate employees' material well-being are associated

¹Some survey evidence suggests that political messages from bosses may influence workers' behavior (e.g., Avenancio-León et al. 2026; Stuckatz et al. 2025). While indicative, self-reported survey responses regarding voting and political participation in general are notoriously unreliable (Achen and Blais 2015; Ansolabehere and Hersh 2012).

with 6.11 percentage point higher turnout, whereas those with lower and more remote stakes are associated with a difference of only 1.18 percentage points.

The difference between high- and low-material stake issues suggests that employees' decision to mobilize is contingent upon the nature of the political issue. To further probe scope conditions, I conduct a similar analysis of voter turnout in elections for the U.S. House of Representatives from 2014 to 2022. Firms donate to political candidates to build relationships that can expand access to politicians (Kalla and Broockman 2016) and potentially unlock strategic advantages (Werner 2017). But whereas ballot questions ask voters to weigh in on discrete, one-off policy proposals—many of which have direct and highly specific relevance for workers in specific industries or firms—the link between voting for a particular candidate and an employee's material well-being is far more distant. To determine whether employees mobilize to support firms' efforts to build connections with politicians, I look at 905 corporate political action committees (PACs), sponsored by 808 publicly traded companies, which donate to House candidates during this period. Across these companies, I analyze voting turnout for over 2.1 million workers in 376 House districts. Using the de Chaisemartin and D'Haultfœuille (2023) difference-in-differences estimator to account for the staggered and non-absorbing nature of firms' decisions to start or stop funding specific House candidates, I find no evidence that worker turnout is associated with firms' decisions to start or stop funding local House candidates.

Together, these findings constitute the first evidence that employees can and do mobilize in support of firms' strategic goals. For relatively large employers in close-run elections, employees' own votes—combined with potential activation of friends, family, neighbors, and other social contacts—could in and of themselves influence results. The potential importance of employees is not limited to elections decided by razor-thin margins. By demonstrating that employees can and do politically mobilize to support firms' strategic goals, this evidence suggests that employees may also support firms in other domains and institutional settings, providing firms with both direct employee lobbyists (Hertel-Fernandez 2017, 2018) and potentially indirect structural power over policymakers dependent upon public support and votes (Lindblom 1977; Bombardini and Trebbi 2011).

This paper makes three contributions. First, it contributes to CPA research, which has largely prioritized research into lobbying and campaign finance rather than less-easily quantifiable measures such as constituency building (Katic and Hillman 2023). Whereas existing studies of constituency building have tended to emphasize external firm partnerships with non-governmental organizations or

grassroots/astroturf campaigns to appeal to the public at large (Walker 2014; Wen et al. 2024), I provide large-scale behavioral evidence which suggests that firms can also rely upon support from internal constituencies. Second, I identify when employees are most likely to mobilize in support of firms. Most significantly, I find that employees' mobilization is far greater when they face more significant material stakes, suggesting that mobilization is plausibly driven by shared mutual interest, rather than necessarily by employer coercion or exploitation (Avenancio-León et al. 2026; Frye et al. 2025; Hertel-Fernandez 2017, 2018). Third, I reposition the role of employees within the broader nonmarket strategy literature. Existing research has often treated employees as a constraint whose reactions to firms' political activity must be managed (Burbano 2021; Hurst and Lee 2025; McKean and King 2024; White et al. 2025). Here, I show that employees can also contribute positively to firms' political strategies.

2 Theory and Related Literature

2.1 Corporate Political Activity

Strategy research emphasizes that firms' ability to shape the nonmarket environment is a major component of performance and strategic success (Baron 1995a,b, 2012). Many key institutional features of the nonmarket environment are set by government policy. As such, firms deploy a variety of corporate political activity (CPA) measures to attempt to influence political outcomes to their own strategic advantage (Hillman and Hitt 1999; Hillman et al. 2004). Much of the CPA research is situated within the "market for public policy" theoretical framework, which posits that firms offer useful resources that are valued by policymakers in exchange for policymakers' assistance and support in pursuing firms' strategic goals (Bonardi et al. 2005; Dorobantu et al. 2017; Grossman and Helpman 1994; Hillman et al. 2004; Lenway et al. 2022; Mellahi et al. 2016). Most research into CPA focuses on the exchange of two types of resources: money (i.e., campaign finance) and information (i.e., lobbying) (Bombardini and Trebbi 2020; Garlick et al. 2025; Hall and Deardorff 2006; Katic and Hillman 2023).

While it has received far less scholarly attention than lobbying and campaign finance, public support is also a valuable resource for firms. First, as previously noted in the introduction, some public policy issues are settled directly or indirectly via elections. In direct democracy elections (i.e., ballot questions), public support can directly determine public policy which can unlock strategic opportunity or enact roadblocks and obstacles. Elections also are used to choose representatives to serve in public office,

which in turn indirectly affect whether policies favorable to firms are enacted.

Public support can also be valuable outside of an immediate election context (Katic and Hillman 2023). Policymakers—regardless of whether they are elected or appointed—are accountable to the public and care about public support. As a result, firms can gain an advantage if they are able to successfully mobilize members of the public to support their preferred policies. Within the market for public policy, policymakers respond better to firms which can deliver valuable goods. Organizing large groups to engage in costly actions—such as attending public meetings, organizing protests or rallies, sending letters to policymakers, or turning out to vote—can convey to policymakers that firms’ preferred outcomes have a broad base of support. These costly signals can thus signal to policymakers that they can benefit from delivering favorable policies or suffer costs if they fail to do so (Kollman 1998; Murphy et al. 2024; Walker and Rea 2014). This can translate into influence. For example, studies have shown that legislators are more willing to schedule meetings with organizations whose representatives have personally donated to their re-election campaigns (Kalla and Broockman 2016), and that firms can also curry favor with policymakers by giving to charities in their home districts (Bertrand et al. 2020). Firms which can plausibly mobilize large numbers of votes could thus also benefit from greater access to policymakers owing to the latent structural power that comes from controlling large concentrated employee voting blocs (Lindblom 1977). Suggestive evidence from Bombardini and Trebbi (2011) suggests that firms with more employees are able to use their employee votes as leverage to gain access to politicians (see also Bombardini and Trebbi 2025).

A growing body of CPA research focuses on how firms can demonstrate public support by mobilizing or building constituency groups. Within this “constituency building” literature, Walker (2012) and Walker and Rea (2014) examine how firms organize grassroots lobbying campaigns that target the public in general, while Wen et al. (2024) focus on how rideshare companies mobilize their customers (i.e., platform users). Related research highlights other methods companies can use to shape public policy through public-facing strategies (Kollman 1998), such as the strategic allocation of corporate philanthropy (Luo et al. 2018; Kaul and Luo 2023; Seo et al. 2021) or CEO activism on sociopolitical issues (Chatterji and Toffel 2019; Hou and Poliquin 2023; McKean and King 2024; Poliquin and Hou 2025). Others study firm partnerships with social activist groups and non-governmental organizations (Dorobantu and Odziemkowska 2017; Gama and Gatignon 2025; Odziemkowska and McDonnell 2024). Murphy et al. (2024) offer a rich account of these processes, analyzing how firms construct “bootlegger

and Baptist” coalitions with values-driven external stakeholders to build broader political support.

2.2 Employees as a Political Support Base

As the constituency building literature explains, public support can be a valuable strategic asset for firms within the market for public policy. Research into constituency-based strategies that mobilize public support in pursuit of firm goals has largely focused on *external* constituencies, such as public grassroots campaigns, customer outreach, or partnerships with social movements. By contrast, *internal* constituencies—i.e., a firm’s own employees—have been largely absent from studies of CPA, despite recognition that employees constitute a core firm constituency (Keim and Zeithaml 1986).

To the extent that employees do feature within research into CPA in any capacity, studies have focused on specialized, elite, or otherwise atypical types of employees. Specialized employees such as professional lobbyists (Jia 2018) or “government affairs” staff (Hall and Sun 2026) play a role in CPA as part of their professional responsibilities to conduct outreach to policymakers. Firms may also take advantage of employees who have informal ties with influential policymakers (Haveman et al. 2017; Jia et al. 2022; Wei et al. 2023) or who are themselves “revolvers” who formerly served in government positions (Egerod and Hollenbach 2024; Katic and Kim 2024). Additional studies looking at specific types of employees focus on the role of employees’ personal political donations to campaigns and political parties. Investigations into employee donors have found that these individual employees frequently allocate their donations in ways that appear to reflect firm strategy rather than solely their personal political allegiances or ideology (Barber IV and Blake 2026; Teso 2025). Firms publicize their donation patterns to their employees so that employees are aware of which candidates their employer supports (Li 2018), and employees respond by increasing their donations to firm-supported candidates (Babenko et al. 2020; Stuckatz 2022a,b; Stuckatz et al. 2025; Teso 2025). Firms, in turn, appear to substitute donations from individual executives for donations from firm-level political action committees (PACs) when political candidates issue public pledges to refuse funding from corporate PACs (Richter and Werner 2017). However, because these studies focus on political donations, they only capture a small proportion of most firms’ workforce.²

²Under the United States’ campaign finance disclosure regime, only donors who give more than \$200 during a two-year election cycle are subject to public reporting requirements. As a result, public disclosure of donors is limited to individuals who are typically older and wealthier (Bonica and Grumbach 2025). Within a corporate context, this means that studies of employees not only capture a very small proportion of overall employees, but also a skewed and unrepresentative subset (Kagan et al. 2026; Stuckatz 2022a; Teso 2025).

Typical rank and file employees have received comparatively little attention. This is surprising for several reasons. First, rank and file employees are far more numerous than employee donors or lobbyists. Given the centrality of employees as a key firm stakeholder, their absence from studies of CPA is striking. Second, even while most research into constituency-building has focused on external constituencies, it was also long recognized that internal constituencies may be an especially promising and attractive political asset for firms. Whereas research into external coalition management often highlights the difficulties of managing these ad hoc arrangements (Murphy et al. 2024; Walker 2012, 2014; Wen et al. 2024), employees are often assumed to be a “naturally aligned” constituency (Keim and Baysinger 1988) that is predisposed to being sympathetic and aligned with their firms’ political goals (Keim and Zeithaml 1986; Lord 2000). Furthermore, employees can be organized cheaply and easily through standard firm communication channels (Hertel-Fernandez 2017, 2018). Workers can even be required to participate in political events as a condition of their employment (Secunda 2010). Third, firms’ political mobilization appears to be a growing phenomenon that has received increased attention in both media and in recent academic research (Avenancio-León et al. 2026; Stuckatz et al. 2025). Employers’ coercion of workers for political ends was a standard feature of 19th century machine politics in the United States, and remains extremely common in electoral systems around the world, especially in less consolidated democracies and transitional regimes (Mares and Zhu 2015; Mares and Young 2016; Frye et al. 2014, 2019, 2025). Although employers in the United States do not appear to use some of the more coercive tactics found in less democratic regimes, scholars have documented that firms routinely use a variety of methods and messages to communicate their preferences to workers, including tacit or implicit threats about the loss of jobs or deterioration of working conditions (Hertel-Fernandez 2018). Given how common it is for workers to face political communication from their managers and supervisors, it is surprising that the strategic potential of such communication has been largely overlooked by strategy and management scholars.

For large firms and/or those with highly geographically concentrated employee bases, the potential for employees to vote as a bloc and deliver specific election outcomes can be a source of power (Bombardini and Trebbi 2011). In addition to the weight of employees themselves, the political influence of the workplace may “spill over” into workers’ families, friends, and neighbors (Hurst et al. 2025; Nickerson 2008), magnifying the impact. While not all companies may be able to deliver enough votes to affect national elections, some firms may be able to make a difference in tight election contests. Hertel-

Fernandez (2018) reports one Florida real estate executive who reached out to Republican (but not Democratic) employees to urge them to vote in the 2000 presidential election (189). Given that his firm employed 8,000 employees and the ultimate margin of victory in the state was only 527 votes, the executive claims—not implausibly—that his actions could have swung the election in favor of George W. Bush. While this example may be atypical, even smaller firms may be able to make a significant difference in election results in lower-turnout elections, such as state and local contests.

2.3 The Workplace as a Political Sphere for Employees

How and why would employees be mobilized to support their firms' strategic priorities? How would they even know what political actions to take? Organizational scholars have long recognized the potential of the workplace to shape workers' political views. A lengthy tradition of scholarship emphasizes class dynamics and the ways in which the material and economic conditions of employment constitute a key driver of political consciousness (Marx 1852, 1867). In addition to sociological and political economy work that emphasizes material and economic considerations, research has also established that the workplace functions as an important social arena that can contribute to political socialization of workers (Selenko et al. 2025). Unions constitute one obvious source of influence, and a number of studies have debated the extent to which unions are able to shape political attitudes and behavior (Flavin and Hartney 2015; Frymer and Grumbach 2021; Hertel-Fernandez 2025; Leighley and Nagler 2007; Yan 2025). Other scholars have theorized that the collaborative nature of workplace interactions can lead to lasting reductions in intergroup prejudice towards stigmatized groups (Allport 1954; Paluck et al. 2019; Pettigrew and Tropp 2006). More recently, scholarship has considered the potentially unique role of the workplace in an era of heightened political polarization and investigated the extent to which workers may be exposed to members of the opposing political party while at work (Chinoy and Koenen 2024; Colonnelli et al. 2025; Frake et al. 2026; Mutz and Mondak 2006; Mutz 2025). Additionally, other studies go beyond the walls of the firm to consider how workplace political socialization may affect workers in ways that impact society more broadly, such as by considering how formal and informal institutions can affect workers' civic engagement and democratic participation (Abrams et al. 2011; Budd et al. 2018; Hurst et al. 2025; Pateman 1970; Perrow 1993).

In addition to over-time socialization, workers are also exposed to explicitly political messages from

their managers and supervisors. Anecdotal reports abound of workers being told by their bosses how they should vote, and even being forced to attend political rallies, meetings, or other events. In the 2012 U.S. presidential election, Republican candidate Mitt Romney explicitly called upon allies in the business community to explain to their workers why they should support him and the Republican party. Multiple business leaders responded by sending letters to their entire employee base warning that a Democratic victory would result in harms to their business, including the loss of jobs, and consequently urging employees to support the Republican party (Frye et al. 2025; Hertel-Fernandez 2018). In the 2016 election, supervisors at a U-Haul location in Arizona required workers to attend a rally supporting Republicans, while casino bosses in neighboring Nevada offered employees paid time off and free box lunches to attend Democratic party caucuses (Frye et al. 2025; Hertel-Fernandez 2018). In the decade since then, the size and scope of companies' political involvement has grown dramatically. Whereas media reports regarding employee mobilization were once dominated by conservative-leaning CEOs contacting employees to urge them to vote for the Republican party, there has been a growing trend for many companies and CEOs to issue public pronouncements of support for progressive social policies associated with the Democratic party (Chatterji and Toffel 2019; Chung et al. 2025; Hurst 2023; McKean and King 2024; Melloni et al. 2023).

Scholars have gone beyond collecting anecdotal reports to gather systematic evidence of the extent to which firms communicate with their workers about politics. While precise figures differ from survey to survey, a picture emerges that clearly suggests that firms routinely attempt to politically mobilize their workers. In the mid-2010s, Hertel-Fernandez (2018) found that nearly half of managers reported attempting to recruit workers into politics, and that 33% of managers gave their employees explicit political guidance that went beyond generic or nonpartisan encouragement to vote or get involved. While Hertel-Fernandez found that only about one in four employees reported being on the receiving end of political messages, a more recent survey by Frye et al. (2025) found that nearly half of all U.S. employees had experienced some exposure to political messaging from a workplace superior. In current working papers, Stuckatz et al. (2025) and Avenancio-León et al. (2026) report similar findings: Stuckatz et al. find that 41% of U.S. employees are aware of their employers' corporate political activities and 28% were personally subject to mobilization attempts, while Avenancio-León et al. find that 68% of employees reported that their employer communicates to them about politics.

These studies typically paint worker political mobilization in a negative light, citing normative

concerns about power imbalances in the workplace between managers and their employees. While they note that explicit coercion appears almost unheard of in the United States, these studies express concerns that firms can constitute “political machines” (Hertel-Fernandez 2018), “vote brokers” (Frye et al. 2025) or “electoral monopsonies” (Avenancio-León et al. 2026) that can put undue and illegitimate pressure on individual workers and even subvert the overall democratic process. Without minimizing these normative social concerns, these striking claims do also give rise to other questions when viewed from a more firm-centric lens. If firms’ influence over their employees can be powerful enough to strike fears about democracy itself—or even, as one recent working paper claims, plausibly have altered the results of U.S. presidential elections (Avenancio-León et al. 2026)—it is reasonable to ask whether, when, and how firms can benefit from deploying this tool.

2.4 When is Mobilization More Effective?

As noted previously, survey evidence suggests that workers are sometimes exposed to political messages while at work. However, few studies have adopted a strategic lens and considered whether and when employees may actually mobilize in support of firms’ strategic goals.

Longstanding theories of voting turnout model individual voters’ decision whether or not to vote as a function of the costs and benefits of voting (Downs 1957; Riker and Ordeshook 1968). In any given election, some voters will vote regardless, and some will never vote. However, there exists a population of voters for whom the decision whether or not to vote is marginal. Different characteristics of elections may likely affect the number of marginal voters and how open they may be to persuasion.

As a result, workers may be more likely to mobilize to vote when they feel that they have greater stakes in the outcome, thus raising the potential benefits of turning out to vote.³ Experimental work on voting behavior demonstrates that messages which emphasize the material stakes and importance of voting can increase voting turnout (Bursztyn et al. 2023; Huber et al. 2022). As a result, we would expect that workers would be more likely to mobilize to vote in elections where they have more at stake.

However, it is not necessarily the case that firms’ strategic interest in a certain election outcome is shared by workers. In some elections, the stakes for workers may be clear. Employees at eye clinics in Oklahoma, liquor stores in Colorado, or casinos in Missouri might all reasonably fear that new

³These benefits may be real, if a worker can potentially change the outcome, or psychological, if he or she simply *feels* that he or she has done so.

competition would result in their employers losing business, affecting their wages and career trajectory. Yet it is not always the case that workers and their employers' material interests are aligned. Firms may also advocate for specific policy priorities that benefit the firm or its managers, but do not necessarily benefit workers, and may even harm them. For example, a change to business taxes might be opposed by business, but have limited salience for workers. Finally, some cases may actually pit employees and their employers against one another (e.g., on issues related to labor rights).

This may be especially true in candidate elections which are held to choose representatives, rather than direct democracy ballot questions where voters approve policies directly. Firms may seek to build strategic ties with politicians. However, many workers may prefer to only support politicians who share their political affiliation, regardless of whether the politician is an ally of their employer (Li 2018). For most adult Americans, party attachment is a durable social identity (Elder and O'Brian 2022; Green et al. 2002) that structures candidate choice (Campbell et al. 1960). Research finds that most adult American voters have strong and consistent partisan identities (Boxell et al. 2024). Partisanship is such a strong social identity that in many cases, voters will even change their policy views and ideological stances to match their partisanship rather than the other way around (Barber and Pope 2019; Dias and Lelkes 2022; Green et al. 2002; Lenz 2012), and may even vote against their direct material interests when doing so would conflict with their partisan identity (Jares and Malhotra 2024). As a result, employees may be far less likely to mobilize in support of their employer when doing so would require them to take steps in support of a particular political party, rather than expressing support for or opposition towards a specific policy.

3 Data

3.1 Overview

Prior studies have used surveys to document the extent to which managers and supervisors target workers with political messaging at work (Avenancio-León et al. 2026; Frye et al. 2025; Hertel-Fernandez 2017, 2018; Stuckatz et al. 2025). To assess whether these efforts are actually successful at changing workers' opinion, these studies have also relied upon survey measures to ask workers if outreach had caused them to change how they voted in the past (e.g., Avenancio-León et al. 2026; Hertel-Fernandez 2018). Unfortunately, self-reported recall of past voting behavior is notoriously inaccurate (Ansolabehere

and Hersh 2012). To better measure whether firms' political activity is associated with increased political mobilization among employees, I instead rely upon actual validated administrative voting records. I am able to do this because voting turnout is a matter of public record in the United States. Although voting *choices* are secret, researchers can see whether any registered voter casts a ballot in any given election.

My empirical strategy thus involves first identifying firms which engage in corporate political activity across different types of elections. To do this, I collect comprehensive public records of firms' campaign finance activity across federal, state, and local U.S. elections. While external corporate spending is not a perfect proxy for firms' internal mobilization, prior work indicates that workers are highly aware of their firms' political stances, including whether and how their firm engages in political spending (Avenancio-León et al. 2026; Li 2018; Stuckatz et al. 2025). I then link firms' corporate spending with individual-level data which links workers' employment history with administrative turnout records, assembled as part of the Politics at Work project (politicsatwork.org, see Frake et al. 2026; Kagan et al. 2026). Using difference-in-differences that account for unique aspects of federal, state, and local election calendars, campaign finance, and geography (Cengiz et al. 2019; de Chaisemartin and D'Haultfœuille 2023; Wing et al. 2024), I test to see whether workers' voting turnout is higher in elections in which their firm is politically active.

I focus on two different types of elections that differ across the dimensions identified in Section 2.4. First, I look at ballot questions. Ballot questions are a form of direct democracy practiced in U.S. states and local governments which ask voters to directly approve or reject policies. Ballot questions differ along several dimensions that can shed light on potential scope conditions. First, ballot questions differ in timing. Some are fielded alongside high-turnout presidential elections or midterms in November, while others are fielded in off-cycle odd years or other months. They also differ significantly across issue areas. Some ballot questions involve core issues with high stakes for both firms and employees (e.g., planning permissions for construction projects or legalization of industries), while others involve issues that have little to do with firms and their workers (e.g., abortion bans or changes to electoral procedures). Finally, ballot questions are non-partisan. This is not to say that ballot questions are non-ideological or that some ballot questions are not associated with one political party's policy positions. However, unlike candidate elections, there is no simple partisan label for voters deciding whether or how to vote on a ballot question.

By way of contrast, I also consider partisan elections for the U.S. House of Representatives. Unlike

ballot questions, these elections are held uniformly in November of every even year. They do not map to specific policy issues, but instead ask voters to choose between Republican and Democratic House candidates (or a third party).

3.2 Data Sources

3.2.1 Corporate Political Activity

Ballot Measures To identify firms which engage in CPA on ballot measures, I start with the universe of all state ballot questions which took place from 2016 to 2024. I collect campaign finance data from the National Institute on Money in Politics (now OpenSecrets) to identify corporate contributors to ballot measure committees. I supplement my state-level coverage with ballot measures from Washington and Colorado, where municipal campaign finance disclosures are available through state-level portals and were scraped programmatically, and from El Paso, TX and Kansas City, MO, identified through manual searches of Ballotpedia’s local ballot measure coverage.⁴

Campaign contribution records are based upon self-reported data. Donors provide their name and contact information, and the ballot question campaigns report to relevant state authorities. Unfortunately, campaign finance regulations enforce no standards on reporting which require contributors to produce a consistent name or identifier, which can lead to confusion across name variants, subsidiary-parent relationships, and other sources of ambiguity (Shanor et al. 2022). Additionally, contribution records in all states do not always reliably distinguish between individual contributors, for-profit companies, other political campaigns, advocacy groups, and other types of contributors. To produce standardized names focused only on for-profit companies, I use an LLM-assisted pipeline to identify corporate contributors. Full details of this production pipeline are described in Appendix D.

House Elections For House elections, I collect records on donations by corporate political action committees (PACs) from OpenSecrets. Whereas linking ballot committee donors requires manual matching, I am able to rely upon an existing PAC-to-Compustat match published by Christensen et al. (2022, 2023).

⁴Ballotpedia covers local elections in the 100 largest municipalities.

3.2.2 Employment Histories

Individual workers' employment histories come from Revelio Labs, which aggregates worker employment histories from LinkedIn. Data from Revelio are increasingly used for research in management and organizational studies, as well as other social science disciplines (e.g., Briscoe and DesJardine 2026; Hurst et al. 2025; Mohliver and Raines 2024; Wang and Zhang 2026).

3.2.3 Voter Records

To understand these workers' political behavior, I rely upon administrative data records in the form of U.S. voter files. In the United States, individuals' vote turnout is a matter of public record. Voter file data contain details of registered voters' turnout history, partisan affiliation, and demographic information (Hersh 2015). However, voter files contain no information on employment, which has historically limited their use in management and strategy research. I overcome this limitation by relying upon detailed individual-level microdata from the Politics at Work project (politicsatwork.org), an ongoing research initiative linking employment records to administrative voter files.⁵ The voter file I use comes from L2, a nonpartisan data vendor, and contains approximately 180 million registered voters with their complete turnout history across all election types.

3.2.4 Election Maps

The House election research design depends upon workers being correctly assigned to the House district in which they were eligible to vote in each election. To ensure that voters are mapped to the correct House district in each election, I rely upon district shapefiles from the Census Bureau's TIGER/LINE releases. In most cases, House districts remain constant from 2012–2020, with a significant number of districts being re-drawn in 2022 following the decennial Census. A smaller number of House districts in certain states were re-drawn during the 2010s mid-decade due to court decisions.

⁵Other Politics at Work research projects include Hurst et al. (2025); Frake et al. (2026); Kagan et al. (2026); White et al. (2025).

3.3 Panel Construction

3.3.1 Worker Data: Linking Employment Records with Voting Records

Revelio Labs and the L2 voter file lack a common joining key, such as a social security number or date of birth. Furthermore, names on LinkedIn may differ from legal names recorded in voting records. To merge the two, I use the ensemble fuzzy matching procedure described in Kagan et al. (2026) and Frake et al. (2026) as part of the Politics at Work project (politicsatwork.org). Kagan et al. and Frake et al. make use of both longstanding record linkage methods (Enamorado et al. 2019; Enamorado 2021; Fellegi and Sunter 1969) as well as newer LLM-enabled methods (Ornstein 2025).⁶ Because of the enormous scale of potential matches, this procedure means first partitioning potential matches by location circa 2024. In other words, the procedure takes registered voters who were registered to vote in a particular metropolitan statistical area (MSA) in 2024 and attempts to match them with workers who reported their employment location in the same MSA. This reduces the scale of required comparisons while preserving theoretically plausible matches. Second, matching is carried out using probabilistic record linkage following Enamorado et al. (2019), which weights multiple matching fields (name, gender, approximate age) by their discriminatory power. Third, the initial probabilistic match is supplemented with a machine learning approach using large language model embeddings (Ornstein 2025) to capture name variations that string distance measures would miss. The matching procedure is described in detail in Kagan et al. (2026) and Frake et al. (2026) as well as in Frake et al. (2025).

Because the House election analysis requires assigning each worker to the congressional district in which they were registered at each election, I recover contemporaneous addresses from L2’s archived voter-file snapshots. For each election in the 2014–2022 window, I select the state-specific snapshot nearest to election day and join it to the analysis panel on L2’s persistent voter identifier (LALVOTERID), yielding the residential address at which each worker was registered at the time of each election (Appendix E.4 reports the specific snapshot used for each state and election). I then assign each address to a congressional district by performing a point-in-polygon spatial join against the Census Bureau’s TIGER/Line congressional district shapefiles for the appropriate redistricting cycle. For L2 snapshot vignettes missing geographic coordinates, I resolve the voter’s census block from a later coordinate-bearing

⁶Alternative, more deterministic approaches involve iterated matching with increasingly less stringent matching requirements and appear to yield broadly similar conclusions (Chinoy and Koenen 2024).

vintage and assign the census block to the appropriate congressional district.

3.3.2 Linking Workers with Companies

Ballot Questions Because state campaign finance data use non-standardized names and, since many politically active companies are private, lack commonly used identifiers (e.g., Compustat’s GVKEY), I implement a four-tier human-in-the-loop matching cascade involving multiple manual and fuzzy matching techniques. My method relies upon conventional string distance matches to capture minor name variants, semantic embeddings which can capture variants such as abbreviations (Dasanaik 2026; Ornstein 2025), and finally, the knowledge embedded within large language models (LLMs).⁷ I describe the procedure in Appendix D.

House Elections Linking worker records with corporate PACs is comparatively straightforward. Revelio’s mapping contains standardized corporate identifiers, including Compustat GVKEY for publicly traded companies. To link companies with their PAC, I use the FEC-to-Compustat crosswalk produced by Christensen et al. (2022, 2023). Within the PAC linkages provided by Christensen et al., 905 PACs give to at least one House candidate during 2014–2022 and have a non-zero number of matched workers from the Revelio-L2 merge. Because some corporations have multiple PACs associated with different subsidiaries, these 905 PACs map to 808 unique companies.⁸ Companies are identified by the ultimate parent organization reported for each committee. Because Compustat assigns some subsidiaries their own GVKEY, the estimation sample spans 765 GVKEYs, which serve as the clustering unit.

⁷These methods have different strengths and trade-offs. String distance can retrieve obvious variants and minor typos such as “Microsoft Co.” vs. “Microsoft Corp.” vs. “Microsoft” [sic]. Semantic similarity relies upon high-dimensional embeddings and so is often able to retrieve far more distant text strings: for example, “BofA” vs. “Bank of America.” Finally, LLMs contain massive amounts of knowledge about the world and can impressively match subsidiaries and even map companies across M&A or name changes (especially very large commercial models as opposed to smaller local or open weight models). For example, modern LLMs are well aware that “Instagram,” “Meta,” “WhatsApp,” and “Facebook” all refer to the same corporate parent. As a result, LLMs can effectively evaluate and review the performance of other matching methods. A growing literature now demonstrates that LLMs dramatically outperform human coders on a wide range of tasks (Bermejo et al. 2025; Choi et al. 2026).

⁸86 companies are associated with more than one PAC. These include operating conglomerates whose subsidiaries retain their own committees after acquisition, e.g., AT&T (AT&T, DIRECTV, WarnerMedia) and Berkshire Hathaway (nine subsidiary committees). Others are investment firms whose portfolio companies each maintain a committee (e.g., the Carlyle Group and KKR).

3.3.3 Matching

For ballot questions, within each state $\times$ election episode, I match treated employees to control voters using coarsened exact matching (Iacus et al. 2012). Control voters are drawn from a donor pool of employees in the same state whose employers do not mobilize on any ballot measure in the state at any point in the sample. Treated and control workers are assigned to cells defined by partisanship, gender, four-digit NAICS industry, and ten-year age band, with band boundaries at ages 30, 40, 50, 60, 70, and 80. Treated workers in cells without an eligible control are dropped from the estimation sample. Where a cell holds more than ten eligible controls per treated worker, I retain ten controls per treated worker, drawn at random with a fixed seed. Firms with fewer than ten matched treated workers in an episode are excluded from that episode.

Table 1: Ballot Measure Sample: Overall Composition

Unique firms	1,868
Unique ballot measures	303
Statewide	264
Local	39
States	39
Local jurisdictions (in 4 states)	24
Unique elections (jurisdiction $\times$ date)	168
Year range	2016–2024
Firm $\times$ measure $\times$ stance pairs	3,034

Table 2: Ballot Measure Sample: Worker Characteristics

	Treated	Control	Std. Diff.	Equiv. p
N (person-episodes)	1,659,392	5,304,954		
Unique voters	786,321	2,840,527		
<i>Demographics</i>				
Age	49.9 (14.7)	49.9 (14.7)	−0.002	<0.001
Female	0.485	0.484	0.001	<0.001
Male	0.515	0.516	−0.001	<0.001
<i>Partisanship</i>				
Lean Democrat	0.530	0.529	0.001	<0.001
Lean Republican	0.410	0.411	−0.002	<0.001
Independent	0.061	0.060	0.002	<0.001
<i>Employment</i>				
Seniority (1–7)	2.6 (1.6)	2.7 (1.6)	−0.040	<0.001

Notes: A single voter can appear in multiple episodes if their employer contributed to more than one ballot measure; person-episodes is the unit of analysis. Seniority is the Revelio Labs 1–7 scale. Standard difference is difference in means divided by the pooled standard deviation. Equivalent p -value is from two one-sided t -tests (TOST) equivalence procedure (Spenkuch et al. 2023); the reported value is the larger of the two one-sided p -values, under the null that the standardized difference exceeds ± 0.1 standard deviations. $p < 0.05$ indicates that equivalence within the ± 0.1 SD margin can be confirmed.

Table 3: Ballot Measure Sample: Firm Characteristics

<i>Panel A: Summary Statistics</i>						
Characteristic	Firms (N)	Mean	Median	SD	Min	Max
Linked workers per firm $\times$ state	3,004	1,322	128	5,179	1	81,918
Estimated measures per firm	1,868	1.6	1.0	1.4	1	18
<i>Panel B: Industry Composition</i>						
Industry	Firms		%			
Construction (23)	233		12.5			
Professional Services (54)	220		11.8			
Manufacturing (31–33)	211		11.3			
Finance & Insurance (52)	185		9.9			
Health Care (62)	152		8.1			
Real Estate (53)	131		7.0			
Accommodation & Food (72)	97		5.2			
Retail Trade (44–45)	89		4.8			
Agriculture (11)	79		4.2			
Wholesale Trade (42)	77		4.1			
Mining & Extraction (21)	74		4.0			
Utilities (22)	64		3.4			
Arts & Entertainment (71)	61		3.3			
Information (51)	55		2.9

Admin & Waste Services (56)	21		1.1			
Management of Companies (55)	3		0.2			
Other Services (81)	2		0.1			

Notes: In Panel A, some firms are active in multiple states.

Table 4: Ballot Measure Sample: Ballot Measure Characteristics

	<i>N</i>	%
<i>Policy type</i> (all 303 measures)		
Industry Regulation	46	15.2
Electoral & Governance	42	13.9
Education	41	13.5
Tax & Fiscal	37	12.2
Social & Civil Rights	32	10.6
Environment / Energy	27	8.9
Other	23	7.6
Healthcare	21	6.9
Labor & Employment	19	6.3
Housing & Land	15	5.0
<i>Material stake</i> (2,888 statewide firm × measure pairs)		
High	348	12.0
Medium	1,296	44.9
Low	1,244	43.1
<i>Election timing</i> (all 303 measures)		
Presidential	147	48.5
Midterm	96	31.7
Off-year	39	12.9
Other	21	6.9

Notes: Policy type and material stake categories are defined in Appendix F. Policy type is assessed for each ballot measure. Material stake is firm-specific and is defined for each firm × measure pair; the material stake rows cover the 2,888 statewide pairs among estimation-sample firms and estimated statewide measures (local measures are excluded). Presidential, midterm, and off-year elections occur in November; “Other” includes all non-November elections.

Table 5: Corporate PAC Sample: Composition

Corporate PACs (employer-linked)	905
Compustat parents (clustering unit)	825
Employer records	2,471
Workers	3,452,268
Worker-elections	8,750,637
House districts	376
States	49
Elections (2014–2022)	5

Notes: The analysis universe is the 905 employer-linked corporate PACs that fund at least one House candidate during 2014–2022. The remaining rows count the sample after the ten-worker firm-cell floor and the stable-map restriction, before the estimator drops worker–district groups observed in a single election; Table 9 reports the counts each fit uses. Compustat parents are distinct GVKEYs, which can exceed the 808 companies identified by organization name.

Table 6: Corporate PAC Sample: Firm Characteristics

	<i>N</i>	Mean	Median	SD	Min	Max
Distinct employer IDs per PAC	905	8.4	4.0	14.3	1	201
Distinct employees per firm	801	8,899	3,035	18,163	12	201,186
Employee worker-years per firm	801	23,569	7,953	47,652	25	505,098
House districts funded per PAC, by map	905	92.6	43.0	125.5	1	770
Employee worker-years in funded districts per firm	801	9,252	1,285	27,049	0	303,583
House candidates funded per PAC	905	83.1	39.0	110.3	1	709
House candidates already funded by 2012 per PAC	905	58.6	23.0	91.9	0	645
Candidate relationships begun, 2014–2022, per PAC	905	58.2	32.0	70.2	0	392
Candidate relationships ended, candidate still running, per PAC	905	38.7	20.0	44.7	0	261
House candidates funded per district	905	1.02	1.00	0.06	1.00	2.19
Democratic House candidates funded per PAC	905	31.9	13.0	45.9	0	282
Republican House candidates funded per PAC	905	51.2	25.0	67.2	0	430

Notes: *N* is the number of units each statistic is computed over. Giving rows are per PAC (905); workforce rows are per company (801), because a company may sponsor several PACs and aggregating to the company de-duplicates workers. Workforce rows cover all matched workers at each company, 2014–2022, before the floor and stable-map restrictions. House giving is direct candidate contributions (FEC type 24K) to two-party House candidates. “Already funded by 2012” looks back to cycles 2008–2012; “relationships ended” counts a candidate a committee funded and then did not fund at the next election while that candidate was still running.

Table 7: Corporate PAC Sample: Worker Characteristics

	<i>N</i>	Mean	Median	SD	Min	Max
Age	1,640,120	53.2	53.0	14.4	20	100
Female	1,632,458	0.423	0.000	0.494	0	1
Male	1,632,458	0.577	1.000	0.494	0	1
Lean Republican	1,642,277	0.447	0.000	0.497	0	1
Lean Democrat	1,642,277	0.503	1.000	0.500	0	1
Independent	1,642,277	0.050	0.000	0.218	0	1
Seniority (1–7)	1,642,277	2.80	2.00	1.55	1	7

Notes: Statistics are for treated worker-elections, in which the worker’s employer’s PAC funds a House candidate in the worker’s district, matched to the enriched voter panels, which cover a subset of states (1,642,277 of 4,284,414 treated worker-elections).

3.4 Variables

3.4.1 Independent Variable: Employer Political Activity

For the main ballot measure and House election analyses, the treatment variable is defined for each individual worker's employer. A worker is treated if they were employed at a politically active firm. For ballot questions, this treatment applies to all workers in the state or local jurisdiction in which the measure is up for a vote. For House elections, treatment is assigned to workers employed at the firm and who also reside in the district where the firm supports a candidate.

3.4.2 Outcome (Dependent) Variable: Worker Turnout

I define *turnout* by whether a worker turned out to vote in a particular election. L2 records vote turnout in each state snapshot but does not distinguish between cases in which a voter was eligible to vote but declined and cases in which a voter was not eligible (e.g., because they were not yet 18 or were registered to vote in another state at the time). To disambiguate between registered voters who declined to vote and those who were not registered, I use the registration date and code elections prior to the registration date as missing rather than failure to turn out to vote.

3.4.3 Moderating Variables

Ballot Question Election Timing My sample includes ballot questions which were fielded in elections held at different points in the electoral calendar. Ballot questions are most commonly held in November during even years, either coinciding with quadrennial presidential elections or midterm elections. Other elections are held in November of “off-cycle” years (i.e., odd years) and a small number are held at other points throughout the calendar (i.e., not November). Baseline turnout differs dramatically depending upon timing. Presidential-year turnout can exceed 70% in many states, while midterm turnout is somewhat lower and off-cycle elections or those not held in November can be as low as 10–20%. I define four different timing dummy variables: presidential-year Novembers, midterm Novembers, odd-year Novembers, and elections held in other periods.

Ballot Question Material Stake For ballot questions, I measure the extent to which a ballot question proposal has a potential material effect on employees' jobs, income, or working conditions. I code this

using multiple LLM coding agents and rate each firm $\times$ ballot question on a 1–10 scale, as well as a categorical grouping into high (8–10), medium (4–7), and low (1–3). Appendix F describes the full coding procedure.

Ballot Question Policy Domain I define a ballot measure’s *policy type* as its primary substantive policy domain. I classified each measure from its description using a ten-category codebook. Appendix F provides the full procedure.

3.4.4 Other Variables

Worker Partisanship Partisanship is used to match treated workers with potential controls, as well as in split-sample analyses of turnout differences in partisan House elections. Because prior literature suggests that most unregistered or putatively “independent” voters display consistent “lean” towards one of the two major U.S. parties—and because voters in some states do not register by party—I use imputed partisanship measures based upon the method described by Frake et al. (2026) and Kagan et al. (2026), which is in turn based upon techniques developed by Brown and Enos (2021). These imputed measures incorporate official party registration in the majority of the states, along with past voting history in partisan primaries. In cases where explicit partisan labels are entirely absent, the method relies upon Bayesian forecasts that incorporate local geography and demographics.

Worker Age Workers’ age comes from official dates of birth from the L2 voter file.

Worker Gender Individual workers’ gender comes from L2.

Employer NAICS Codes I rely upon Revelio’s industry classifications for firms. Revelio assigns NAICS codes to each employer. When aggregating multiple subsidiaries of the same firm, NAICS codes may differ across different subsidiaries.

4 Ballot Questions

4.1 Estimation Strategy

My sample consists of 303 unique ballot measures. Because these elections took place across 168 unique elections in 39 states which differ in terms of timing, they do not follow a common unit-time structure. Because of differences in election timing and state-by-state election schedules, I do not aggregate across all elections. Instead, I use the stacked difference-in-differences approach of Cengiz et al. (2019). This means that turnout in a specific election is compared with prior elections which took place in the same state and in the same timing period—presidential elections with prior presidential elections, midterms with prior midterms, etc.

I fit the following weighted linear probability model:

$$Y_{is\tau} = \beta (D_{is} \times \text{Post}_{s\tau}) + \alpha_{is} + \lambda_{s\tau} + \varepsilon_{is\tau}, \quad (1)$$

where $Y_{is\tau}$ equals one if voter i in episode stack s votes in relative election period τ ; D_{is} indicates that the voter belongs to the treated cohort in that stack; and $\text{Post}_{s\tau}$ equals one at the treatment election ($\tau = 0$) in the headline window, $\tau \in \{-3, -2, -1, 0\}$. Because different election families (i.e., timing) have very different levels of turnout (i.e., presidential years vs. off-cycle), I define each stack's relative unit time only for elections of the same type (for example, a 2022 midterm election would be compared with 2018, 2014, and 2010). The terms α_{is} and $\lambda_{s\tau}$ are voter-by-stack and stack-by-relative-period fixed effects, respectively.

I estimate equation (1) by weighted least squares, first fitting each stack using the individual matching weights used in the CEM and then re-weighting so each stack receives equal weight when aggregated. The coefficient β is therefore the pooled difference-in-differences estimate of the turnout difference at the treatment election. Standard errors are clustered by firm and episode stack.

4.2 Results

4.2.1 Main Results

Table 8 presents my results. Column 1 reports the pooled estimate. Employees at politically active firms turn out to vote at rates 1.86 percentage points higher than matched employees at firms that are not

Table 8: Employee Mobilization and Voter Turnout: Stacked Difference-in-Differences

Voter $\times$ Episode FE	Yes	Yes	Yes	Yes
Episode $\times$ Period FE	Yes	Yes	Yes	Yes
Clustering		Firm + Episode		

Notes: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Each column reports a stacked difference-in-differences regression on the combined statewide and local sample. Column 2 uses presidential-year November as the timing reference and retains midterm November, off-cycle November, and all other election dates. Columns 3–4 restrict to episodes with a classified treated firm–measure stake; the continuous interaction is the change per one-point increase on the 1–10 scale, and the categorical specification uses low stake as the reference.

politically active (95% CI [1.23, 2.50]). Appendix A.3 reports the event-study form of this specification.

While the overall estimate is positive and significant, its size varies significantly with context. Column 2 interacts the main term with the timing of the election, using presidential-year November elections as the reference category. The estimate is smallest in these high-salience presidential elections (0.9 percentage points), where turnout is already high and firms may have limited headroom to turn out additional marginal voters. Relative to presidential elections, the estimate is 1.3 percentage points larger in midterm elections (95% CI [0.4, 2.2]). The point estimates for off-cycle November elections (2.6 percentage points) and for elections held outside of November (2.6 percentage points) are larger still, but they are less precisely estimated and their confidence intervals include zero.

In addition to timing, the content of the issue also appears to matter. Column 3 interacts the main term with the 1–10 material stake score. Each additional point on the scale is associated with a turnout difference that is 0.52 percentage points larger (95% CI [0.19, 0.85]). Column 4 replaces the continuous score with stake categories, using low-stake ballot questions as the reference category. For ballot questions with low material stakes for employees, turnout is 1.18 percentage points higher. The estimate for medium-stake questions is indistinguishable from the low-stake estimate (a difference of 0.42 percentage points), whereas the estimate for high-stake questions is 4.93 percentage points larger (95% CI [1.94, 7.92]), for a total difference of 6.11 percentage points. This difference is comparable in magnitude to the 7–8 percentage point increase in turnout that Enos and Fowler (2018) attribute to the combined efforts of the 2012 presidential campaigns in the most heavily targeted battleground states.

4.2.2 Additional Results

Appendix A reports a number of additional analyses. Figure A2 depicts the estimates shown in Table 8 (i.e., election timing and material stake), as well as additional subgroup estimates. I find no significant differences by geography (i.e., state vs. local elections) or the origin of the ballot question (i.e., whether they were placed on the ballot as a result of a citizens' petition or referred by the state legislature). I also find no difference by workers' seniority, as measured by Revelio's 1–7 seniority measure.

As a supplement to the material stake analysis, I also classify ballot questions into ten separate issue domains. Appendix F documents the coding rules I use to classify ballot measures by issue. The results appear mostly consistent with material stake serving as an important moderator, although with ten

separate dummy variables, few estimates differ from one another at conventional significance levels. Issue domains where firms and workers are unlikely to share clear material stakes, such as social and civil rights questions, have the smallest estimated turnout difference, whereas the largest is for environmental and energy questions, many of which involve permitting or project approvals that have the potential to create jobs for workers.

4.2.3 Supplementary Analysis: Direction of Vote

Finally, I also conduct additional suggestive analysis about the *direction* of the vote. Because ballots are secret, I cannot definitively say that increased worker turnout meant that workers voted in the direction favored by their firm. Because individual employees' votes can never be observed, I focus on precincts (voting tabulation districts), and compare across neighboring precincts which differ in the proportion of workers at politically active firms. Because workers of any particular firm are unlikely to ever constitute a significant portion of a given election precinct (which typically range from 1,000–2,000 voters), the contribution of individual workers is likely to be small, but when one considers the potential for secondary persuasion effects to “spill over” (i.e., from workers to family members and close neighbors), it is possible that detectable differences could be found at the precinct level.

Precinct-level data are available in seven states and include 31 ballot questions. I define the exposure variable as the number of politically active workers as a share of the total number of ballots cast on a measure. I exclude measures where firms mobilize on both sides of a ballot question. I compare across all precincts within a state, using Conley spatial-HAC standard errors to account for spatial autocorrelation. Because exposure and outcome are both shares, the slopes are in percentage points of firm-preferred vote share per percentage point of exposure. When comparing all precincts voting on the same measure, a one percentage point increase in exposure is associated with a 4.13 percentage point increase in the firm-preferred vote share, which is statistically significant. However, across-precinct differences may be driven in large part by residential sorting among different types of workers. Comparing precincts in the same county voting on the same measure reduces the slope to 0.48 percentage points ($p = 0.046$). In a more restricted sample, which limits comparisons to adjoining (neighboring) precincts to better account for residential sorting, the slope falls to 0.20 percentage points, just outside the conventional 5% significance threshold ($p = .054$). While these results are cross-sectional and associational rather than

causal, they are consistent with workers' mobilization manifesting not just as additional *turnout*, but also potentially shifting vote shares in favor of firms' preferred outcomes. Full results and details are available in Appendix B.

5 House Elections

5.1 Estimation Strategy

My analysis of House elections is limited to publicly traded firms with a political action committee (PAC). Because the types of companies which have an established PAC differ from politically inactive companies by definition, my analysis focuses not on comparing between companies with PACs and companies without PACs, but instead exploits spatial and temporal variation in giving among companies that do have PACs. During the sample period (2014–2022), each corporate PAC funds an average of 83 distinct candidates for the U.S. House of Representatives (see Table 6). Because House members are assigned to one of 435 geographical districts, this means that some workers at firms with PACs have the opportunity to mobilize in support of a candidate backed by their firm, while others do not have a firm-supported candidate in their district for whom they could vote. Figure 1 displays the extent of PAC funding in each district from 2014 to 2022. Darker shades denote districts where candidates received support from a greater number of unique PACs. Some districts receive consistently large numbers of donations. For example, Oregon's 2nd district (in the east of the state) received among the highest number of corporate PAC donations because Greg Walden, a Republican, chaired the Committee on Energy and Commerce in 2017–2018.

Identification comes from *changes* in firms' PAC donations within a district from election to election. Figure 2 shows, for each pair of consecutive elections, where corporate PACs start funding a House district they had not funded in the previous election (left) and where they stop (right). To estimate the association between PAC spending and employee turnout, I target the following specification,

$$y_{it(f,d)} = \beta D_{it} + \mu_i + \lambda_{dt} + \varepsilon_{it}, \quad (2)$$

where $y_{it} \in \{0, 1\}$ reflects whether worker i at firm f and living in district d votes in election t , D_{it} is

a treatment indicator,⁹ μ_i and λ_{dt} are worker and district $\times$ election (race) fixed effects, respectively, and ε_{it} is an error term. By including district $\times$ election (race) fixed effects, I limit the comparison to workers residing in the same House district, to account for race-specific competitive dynamics. Because treatment status is both staggered and non-absorbing (i.e., corporate PACs can and do start and stop donating to candidates in a given district), I estimate Equation 2 via the de Chaisemartin and D’Haultfœuille (2023) difference-in-differences estimator, which is built around “switchers.”¹⁰ As in Equation 2, comparisons are limited to workers within the same district. My main reported specification focuses on “entries”—i.e., firms which begin funding a district having not done so in the previous election, but I also report “exits” and the pooled estimate across both entries and exits. Because the de Chaisemartin and D’Haultfœuille (2023) estimator does not directly admit fixed effects, I include a nonparametric district-specific time trend in lieu of λ_{dt} . Standard errors are clustered at the company level; I limit my sample to firm $\times$ district cells with at least ten workers.

Figure 1: Committees funding each House district’s race, by election. Per-district count of corporate committees that gave to the district’s House candidate in each cycle. Lower 48 only; Alaska, Hawaii and DC are dropped for the equal-area frame.

⁹Worker i ’s treatment status is technically given by $D_{f(i,t)d(i,t)t}$, which I abbreviate to D_{it} for simplicity.

¹⁰A firm-district is a switcher at t if $D_{fdt} \neq D_{fdt-1}$.

Figure 2: Committees starting and stopping funding by House district. Left: committees funding the district's race this election that did not fund it at the previous election. Right: committees that funded it at the previous election and not this one. Shared scale. For 2020-2022, districts are counted only where the incumbent ran again under the same district number; the others (left blank) are redrawn seats. Lower 48 only.

5.2 Results

Table 9 reports the main estimates. When a firm’s PAC begins funding the House candidate in a worker’s district, the estimated change in the worker’s turnout is -0.26 percentage points (95% CI $[-0.74, 0.22]$). The estimates for exits, when a PAC stops funding the candidate in a district (0.73 percentage points, 95% CI $[-0.76, 2.22]$), and for entries and exits pooled (0.57 percentage points, 95% CI $[-0.68, 1.83]$) are also indistinguishable from zero.

Table 9: Employee turnout and the firm’s PAC entry into the employee’s own congressional district

	<i>Dependent variable: turnout</i>		
	(1) Entries	(2) Exits	(3) Pooled
Effect on turnout (pp)	-0.26 (0.25)	0.73 (0.76)	0.57 (0.64)
Observations	7,075,505	7,075,505	7,075,505
Workers	2,108,563	2,108,563	2,108,563
House districts	376	376	376
Elections	5	5	5
States	49	49	49
Compustat parents	765	765	765
Switching units	77,866	383,419	461,285

Notes: All columns are estimated with the de Chaisemartin and D’Haultfoeulle (2023) switching estimator. Column (1) includes firm–districts that switch into funding. Column (2) includes firm–districts that switch out of funding. Column (3) pools both. Standard errors are clustered at the Compustat parent company. $*p < 0.1$; $**p < 0.05$; $***p < 0.01$. p -values are two-sided, from the coefficient and its clustered standard error. Counts are those each fit uses: worker–district–parent groups observed in at least two elections, a subset of the 3,452,268 workers in Table 5.

5.2.1 Partisan Alignment

The main specification considers the turnout difference across all workers. However, workers who belong to the opposing party relative to the candidate that their firm supports may not be motivated to turn out, while those who belong to the same party as the candidate may be more likely to turn out. To account for this, I re-fit Equation 2 separately for each of the four combinations of workers’ partisan lean (Democratic or Republican) and the party of the funded candidate, pooling entries and exits. Each fit excludes independents and any firm–district that ever funded a candidate of the other party. Table 10 displays the results. None of the four estimates is distinguishable from zero. Among workers whose partisan lean matches the party of the funded candidate, the change in turnout is -0.05 percentage points for Democratic workers when the firm funds a Democratic candidate (SE 0.34) and

0.71 percentage points for Republican workers when the firm funds a Republican candidate (SE 0.91). The corresponding cross-partisan estimates are -0.23 percentage points for Republican workers when the firm funds a Democratic candidate (SE 0.46) and 0.31 percentage points for Democratic workers when the firm funds a Republican candidate (SE 0.48).

Table 10: The turnout effect by the funded candidate's party and the worker's partisan lean, pooled over entries and exits

	<i>Dependent variable: turnout</i>			
	Democratic candidates		Republican candidates	
	(1) Democrats	(2) Republicans	(3) Democrats	(4) Republicans
Effect on turnout (pp)	-0.05 (0.34)	-0.23 (0.46)	0.31 (0.48)	0.71 (0.91)
Observations	2,638,034	1,701,482	2,231,549	2,540,703
Workers	819,930	514,671	702,342	742,456
House districts	375	375	376	376
Elections	5	5	5	5
States	49	49	49	49
Compustat parents	749	751	759	759
Switching units	108,648	56,144	103,187	167,725

Notes: All columns are estimated with the de Chaisemartin and D'Haultfœuille (2023) switching estimator. All columns pool both entries (firm–districts which switch into funding) and exits (firm–districts which switch out of funding). Standard errors are clustered at the Compustat parent company. * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$.

5.2.2 Alternative Samples to Account for Endogenous Selection Into Treatment

A worker's treatment status may change for two reasons. First, it may change as a result of the worker's own decision to change employers or to move across district lines. Second, it may change as a result of a firm's decision to start or stop giving to a particular candidate in a particular district. One concern is that firms' decisions about which candidate to support may be in some way endogenous if they are related to firms' expectations of how their employees may react. Li (2018) shows that PACs' spending allocations are constrained by the partisan preference of firm employees. While her study focuses on elite donor employees—who arguably have far more leverage and visibility—it is also possible that firms may consider the partisanship of their employees within a certain district in deciding whether or not to support a candidate.¹¹

¹¹In all likelihood, this would seem to bias results in favor of finding a positive estimate. Presumably, firms would be more likely to support candidates who are likely to be popular among their employees who reside in their district, rather than supporting candidates who are unpopular among their employees.

To better account for this potential endogenous selection into treatment, I re-fit Equation 2, disaggregating based upon multiple mechanisms by which treatment may occur. First, Column (1) looks only at treatment changes which occurred because firms started or stopped funding candidates in a worker’s district. Second, in Column (2), I look only at treatment changes which occurred because workers changed employers without moving across district lines, rather than firms deciding to start or stop funding candidates. Third, I look at House members who move committee assignments to join (or leave) committees with oversight over a firm’s specific industry, another plausibly exogenous driver of firms’ donation behavior (Fourirnaies and Hall 2018; Powell and Grimmer 2016). To determine which committees are relevant for different industries, I adopt the measure designed by Teso (2025) (see also Bertrand et al. 2020) and identify the important committees for each industry (2-digit NAICS) as those which receive the largest lobbying expenditures from companies in that industry. As such, Column (3) shows only changes in treatment status which are induced by a House representative joining or departing a committee assignment with oversight over a specific industry.¹² Appendix C.5 describes the committee-assignment events behind Column (3). Table 11 reports the results. Restricting to treatment changes caused by firms starting or stopping funding leaves the entry estimate essentially unchanged (−0.27 percentage points, 95% CI [−0.77, 0.22]). Entries driven by workers switching employers, which do not depend on the firm’s allocation decision, yield an estimate of 0.63 percentage points (95% CI [−0.31, 1.58]), and entries induced by committee assignments yield −0.03 percentage points (95% CI [−0.64, 0.57]). The exit and pooled estimates in each column are likewise indistinguishable from zero.

5.3 Other Results

Appendix Figure A6 plots the entries estimate by election relative to entry. Appendix C.2 reports an alternative triple-difference specification that also compares the same firm’s workers across districts within a state. Appendix C.3 reports two further sample restrictions, one excluding firms that also fund a Senate candidate in the worker’s state and one limited to races in which the sitting member stood again. None of these estimates is distinguishable from zero.

¹²Following Teso (2025), for important general committees without specific industry relevance (i.e., Appropriations and Energy and Commerce), I use subcommittee assignments.

Table 11: Employee turnout by the mechanism that changed exposure

	<i>Dependent variable: turnout</i>		
	(1) Firm entry / exit	(2) Employer change	(3) Committee role
Effect on turnout, entries (pp)	-0.27 (0.25)	0.63 (0.48)	-0.03 (0.31)
Effect on turnout, exits (pp)	0.84 (0.77)	-0.06 (0.40)	-0.15 (0.45)
Effect on turnout, pooled (pp)	0.67 (0.66)	0.20 (0.31)	-0.09 (0.27)
Observations	6,806,595	4,864,568	6,767,788
Workers	2,019,481	1,504,617	2,007,574
House districts	376	376	376
Elections	5	5	5
States	49	49	49
Compustat parents	765	786	765
Switching units	439,231	27,716	458,789

Notes: All columns are estimated with the de Chaisemartin and D'Haultfoeulle (2023) switching estimator. Column (1) includes workers for whom the change in treatment status occurs because a firm begins or ends funding a race in their district. Column (2) includes workers whose treatment status changes because they change employers without moving districts. Column (3) includes districts where the incumbent in the district joins or leaves a committee with relevance for a specific company. Standard errors are clustered at the Compustat parent company. * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$.

6 Discussion

Firms often must rely upon public support to pursue strategic goals and defend against threats. Corporate political activity research identifies constituency building as a potentially effective tactic (Hillman and Keim 1995). Existing research has concentrated on how firms build external constituencies through public relations or alliances with social movements and non-governmental organizations (Walker 2014; Wen et al. 2024; Odziemkowska and Zhu 2025). Internal constituencies—i.e., a firm's own rank-and-file employee base—have received comparatively little attention. While recent research highlights the potential for the workplace to shape employees' political beliefs and behavior, we lack evidence as to whether employees will mobilize to take costly political action in support of firms' strategic goals.

By assembling data on the work histories and voting turnout of millions of workers and linking them with their employers' political activities, I test whether employees turn out to vote at higher rates in strategically important elections. Across 303 ballot questions in 39 states, workers at politically active firms turn out to vote at 1.86 percentage points higher rates than matched workers. The extent of employees' mobilization depends significantly on the type of issue involved. In ballot questions with

high material stakes for employees, worker turnout is 6.11 percentage points higher, versus only 1.18 for ballot questions where comparatively little is at stake for employees. The importance of employees' own interests is further supported by additional analysis. While employees do mobilize to turn out at higher rates in high-stakes ballot questions where their firm spends to advance its strategic goals, employees do not appear to respond by voting at higher rates in support of politicians supported by their firm. In an additional analysis focused on firms' PAC spending, I find no evidence that the onset of PAC funding for a candidate in workers' own House district is associated with increased worker turnout.

The data presented here are limited in several respects. First, the context—voting—is propitious in that it is quantifiable, individually-identifiable measure. While turnout is publicly observable, the direction of vote is not. I present indicative evidence that employees vote in the direction preferred by their firm, but it is not possible to definitively establish that this is the case. Second, while I can observe an association between firms' involvement in specific elections and employees' turnout, I am unable to directly observe the strategic calculations that firms make in deciding when to become politically active (i.e., by donating money to support political campaigns), and whether and how they consider likely employee responses in these decisions. Future research may consider building on earlier work by Li (2018) to further explore firm decision-making in this context. Third, voting is only one of the ways in which employees can support firms' strategic goals. While this study uses voting evidence to establish that employees can and do mobilize politically in support of their firms' strategic aims, future studies can consider alternative methods and institutional settings in which employees' support may also prove strategically advantageous.

In many cases, employees' own votes—even when multiplied by potential secondary mobilization of friends, family, neighbors, and other members of employees' social networks—may not be enough to be decisive in elections. Furthermore, many issues may never be put directly to voters.

These findings make several contributions. First, they extend research on constituency building. Prior studies have emphasized firms' efforts to cultivate external allies and have documented the costs and risks that such partnerships entail (Odziemkowska 2022; Murphy et al. 2024). I extend the scope of research into constituency building by documenting for the first time the strategic potential of workers to politically mobilize in support of firms' strategic goals. Second, these results provide guidance as to the conditions in which workers mobilize. While some existing accounts express concerns that companies exploit asymmetric power relations to pressure or coerce workers to vote against their interests (Hertel-

Fernandez 2017; Frye et al. 2025; Avenancio-León et al. 2026), these results suggest fairly stringent scope conditions. Workers do not mobilize to support firms equally in all circumstances, but instead appear to mobilize for non-partisan issues in which they share stakes with their employer. Finally, these results illustrate a different—and more positive—role for employees to play in nonmarket strategy. Nonmarket strategy literature often views employees as audiences who constrain firm action and whose responses must be managed (Burbano 2021; Hurst and Lee 2025; McKean and King 2024; White et al. 2025). Where employees appear as political resources, they are typically lobbyists, executives, or donors whose contributions supplement those of the firm (Li 2018; Stuckatz 2022a). By highlighting the positive contribution of rank and file employees to firms’ pursuit of their strategic ends, I reaffirm the central role of ordinary employees as a key firm stakeholder.

H.3	Measures in the Precinct-Level Sample	A46

A Ballot Questions: Additional Results

A.1 Sample Composition

Figure A1: Distribution of linked treated workers across company-state cells.

Notes: The histogram contains 2,071 company-state cells with at least 10 distinct linked treated workers. The horizontal axis is logarithmic. Identical local and statewide cells are counted once. Vertical lines mark the median and mean; labels identify the 4 cells with more than 50,000 linked workers.

A.2 Estimates by Moderator

Figure A2: Turnout differences by moderator. Panels report estimates by election timing, material stake, election scope, how the measure reached the ballot, policy type, and job seniority. Every panel is estimated without a reference category, so each point is the estimate for that group rather than a difference from an omitted one. Points are estimated turnout differences in percentage points; bars report 95% confidence intervals. Job seniority splits the Revelio 1–7 scale at level 5. Three panels rest on restricted samples and are not directly comparable to the others: material stake retains only episodes with a classified treated firm–measure stake, measure origin only the statewide episodes the origin corpus covers, and job seniority only workers with Revelio seniority data, with stack weights renormalized after that restriction.

Table A1: Employee Mobilization and Voter Turnout by Election Scope

	<i>Dependent variable: turnout</i>
	Election scope
Treated $\times$ Post (statewide)	0.018*** (0.003)
... $\times$ Local (vs. statewide)	0.007 (0.013)
Num. Obs.	19,193,668
N treated workers	786,321
N control workers	2,840,527
N states	39
N ballot questions	303
N active firms	1617
Voter $\times$ Episode FE	Yes
Episode $\times$ Period FE	Yes
Clustering	Firm + Episode

Notes: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. This table compares the estimated effect of political involvement on ballot measures on worker turnout between statewide elections and local elections.

Table A2: Employee Mobilization and Voter Turnout by Policy Type

	<i>Dependent variable: turnout</i>
	Policy type
Treated × Post (social/civil rights)	0.008 (0.006)
... × Labor/employment (vs. social/civil rights)	0.008 (0.013)
... × Tax/fiscal (vs. social/civil rights)	0.003 (0.010)
... × Industry regulation (vs. social/civil rights)	0.017* (0.010)
... × Electoral/governance (vs. social/civil rights)	0.002 (0.009)
... × Education (vs. social/civil rights)	0.006 (0.007)
... × Healthcare (vs. social/civil rights)	0.004 (0.008)
... × Environment/energy (vs. social/civil rights)	0.037** (0.016)
... × Housing/land (vs. social/civil rights)	0.011 (0.011)
... × Other policy type (vs. social/civil rights)	0.010 (0.011)
Num. Obs.	19,193,668
N treated workers	786,321
N control workers	2,840,527
N states	39
N ballot questions	303
N active firms	1617
Voter × Episode FE	Yes
Episode × Period FE	Yes
Clustering	Firm + Episode

Notes: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. This table compares the estimated effect of firm political involvement on ballot measures on worker turnout across issue areas. Includes both statewide and local ballot questions. Standard errors are clustered by firm and episode. Social/civil rights is the omitted policy category.

Table A3: Heterogeneous Treatment Effects: Job Seniority

	<i>Dependent variable: turnout</i>		
	Pooled	+ Seniority	+ Seniority (cont.)
Treated × Post	0.019*** (0.003)	0.017*** (0.003)	0.015*** (0.005)
Treated × Post × Senior (≥ 5)		-0.002 (0.006)	
Treated × Post × Seniority (1-7)			0.001 (0.002)
Num. Obs.	19,193,668	17,935,336	17,935,336
N treated workers	786,321	785,122	785,122
N control workers	2,840,527	2,836,955	2,836,955
N states	39	39	39
N ballot questions	303	290	290
N active firms	1617	1602	1602
Voter × Episode FE	Yes	Yes	Yes
Episode × Period FE	Yes	Yes	Yes
Clustering		Firm + Episode	

Notes: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Each column adds a single interaction to the pooled stacked DiD specification. Seniority columns restrict to workers with Revelio seniority data. Column 2 splits at senior level ≥ 5 on the Revelio 1–7 scale. Column 3 uses the continuous 1–7 scale.

Table A4: Employee Mobilization and Voter Turnout by How the Measure Reached the Ballot

	<i>Dependent variable: turnout</i>
	Procedural origin
Treated × Post (citizen-initiated, 191 episodes)	0.019*** (0.004)
... × Legislatively or automatically referred (99 episodes)	-0.002 (0.006)
... × Veto referendum (15 episodes)	-0.005 (0.014)
Num. Obs.	17,457,154
N treated workers	778,921
N control workers	2,815,921
N states	39
N ballot questions	264
N active firms	1575
N episodes coded	305 of 344
Voter × Episode FE	Yes
Episode × Period FE	Yes
Clustering	Firm + Episode

Notes: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$. Standard errors are clustered by firm and episode.

A.3 Event Study

Figure A3 replaces the post-period indicator of equation (1) with one indicator per relative election period, $\tau \in \{-3, \dots, +2\}$, with $\tau = -1$ as the reference period. The pre-period coefficients are -0.17 pp at $\tau = -3$ (95% CI $[-0.99, 0.65]$) and 0.14 pp at $\tau = -2$ (95% CI $[-0.59, 0.86]$). The treatment-period coefficient is 1.86 pp (95% CI $[1.28, 2.44]$). Under the relative-magnitude sensitivity analysis of Rambachan and Roth (2023), which bounds the post-period violation of parallel trends at $\bar{M}$ times the largest pre-period violation, the treatment-period confidence set is $[0.74, 2.89]$ at $\bar{M} = 1$ and $[0.33, 3.29]$ at $\bar{M} = 1.5$, and it first includes zero at $\bar{M} = 2$ ($[-0.10, 3.72]$). The coefficients at $\tau = +1$ (0.66 pp, 95% CI $[-0.01, 1.34]$) and $\tau = +2$ (0.91 pp, 95% CI $[0.12, 1.70]$) combine any persistence of the original campaign with renewed mobilization by employers that campaign again in later elections.

Figure A3: Event study of turnout around the mobilization election. Points are coefficients on treated $\times$ relative-period indicators from equation (1) with the post indicator replaced by period indicators; the reference period is $\tau = -1$. Bars are 95% confidence intervals, with standard errors clustered by firm and episode stack; the hollow point marks the reference period. Relative periods count elections of the same family. The vertical axis is on the 0–1 turnout scale.

A.4 Leave-One-State-Out

The estimation sample is unevenly distributed across states. Because of differences in state constitutions, ballot questions are far more common in western states. As a result, California, Washington, and Colorado supply 146 of the 344 episodes. To ensure that results are not driven by a single state, Figure A4 displays a “leave-one-state-out” analysis in which I refit the headline specification 39 times, each time dropping every episode in one state.

The estimate ranges from 1.62 to 2.04 pp against 1.86 pp in the full sample, and every interval excludes zero. Dropping the largest states (California, Washington, and Colorado) moves results upwards. The largest downward movement comes from dropping Maine, which has several large episodes related to the largest electrical utility in the state, whose employees show very large turnout differences.

Figure A4: Leave-one-state-out refits of the headline specification. Each row drops every episode in the named state and refits; point area is the number of episodes dropped, and bars report 95% confidence intervals with firm- and episode-clustered standard errors. The solid vertical line marks the full-sample estimate of 1.86 pp.

B Ballot Questions: Direction of Vote (Precinct Analysis)

B.1 Variables

Precinct Share of Politically Active Workers For the precinct-level analysis, the exposure variable is continuous and defined by the number of politically active workers as a share of the total number of ballots cast on the measure.

Precinct Vote Share For each measure and precinct, I define the outcome as the firm-preferred share of ballots cast on the measure. I use the affirmative share when the firm supports the measure and one minus that share when the firm opposes it. Both the affirmative and the total count come from the official returns in Table A16; the denominator is ballots cast on that measure. Because exposure and outcome are both shares, the estimated slope is in percentage points of firm-preferred vote share per percentage point of exposure.

B.2 Estimation Strategy

Table A5 reports three specifications.

My first specification estimates

$$y_{pm} = \beta x_{pm} + \lambda_m + \varepsilon_{pm} \quad (\text{A1})$$

on 169,701 precinct $\times$ measure cells, where y_{pm} is the firm-preferred vote share in precinct p on measure m and x_{pm} is the share of ballots in precinct p cast by workers at politically active firms on measure m . Measure effects, λ_m , ensure that the slope is estimated from differences across precincts voting on the same measure rather than from differences in average support across measures.

Because the first specification (Equation (A1)) is cross-sectional, residential sorting and other differences in precinct composition could explain observed differences in vote results. The second specification replaces λ_m with a county $\times$ measure effect, so the comparison is between precincts in the same county voting on the same measure, to better account for potential residential sorting. It defines 4,746 county $\times$ measure groups, of which 1,833 contain the exposure variation that identifies the slope, covering 107,265 cells and 66.5% of ballot weight; 1,221 of the remaining 2,913 are singletons.

Finally, I fit an additional specification that limits comparisons to immediately adjoining precincts. Because precincts are fairly small (typically 1,000 to 2,000 people), adjoining precincts are likely to have similar populations. Figure A5 illustrates the adjoining-precinct design and the variation in workforce exposure across neighboring precincts.

This adjoining precinct specification estimates

$$\Delta y_{ijm} = \alpha_m + \beta \Delta x_{ijm} + \varepsilon_{ijm}, \quad (\text{A2})$$

where

$$\Delta y_{ijm} = y_{im} - y_{jm} \quad \text{and} \quad \Delta x_{ijm} = x_{im} - x_{jm} \quad (\text{A3})$$

and is based on 164,740 nonzero within-measure pair differences, drawn from the precinct adjacency graph of the relevant geometry layer. Each pair is oriented so that i is the higher-exposure precinct.

Standard errors are Conley spatial heteroskedasticity- and autocorrelation-consistent, computed at the precinct centroid. I report no clustered standard errors. The main table reports the 5 km Bartlett bandwidth. Table A6 reports 10 and 25 km under both Bartlett and uniform kernels for every specification. As a second check I resample spatial blocks with replacement, using a grid at the Conley bandwidths

rather than administrative units, and recompute the estimate on each draw. Grid blocks are used deliberately: blocking on counties would reintroduce the assumption that county boundaries track the spatial dependence, which is the assumption the move to Conley standard errors rejects. Table A7 reports the resulting intervals beside the Conley ones.

B.3 Results

In Column (1) the exposure slope is 4.13 (95% CI [3.202, 5.050]). Column (2) compares precincts in the same county voting on the same measure, and the slope falls to 0.48 (SE 0.24, $p = 0.046$). The adjoining-pair slope is 0.20 (95% CI [−0.003, 0.406]). The estimate is much smaller than the precinct-cell slope and falls just outside the conventional 5% significance threshold ($p = .054$); its Conley 95% confidence interval narrowly includes zero. The 10 and 25 km spatial block-bootstrap percentile intervals exclude zero, although the corresponding two-sided bootstrap p -values are .055 and .063. Appendix Table A6 reports alternative bandwidths for different Conley standard errors, and Table A7 reports spatial block bootstrap.

Table A5: Firm Workforce Exposure and Neighborhood Vote Direction

	Levels		Adjacent precinct pairs
	(1)	(2)	(3)
Mobilizing workers / ballots cast	4.13*** (0.47)	0.48** (0.24)	0.20* (0.10)
<i>Fixed effects</i>			
Measure	✓	✓	✓
County × measure	—	✓	—
Ballot measures	31	31	31
States	7	7	7
Observations	169,701	169,701	164,740

Notes: Standard errors in parentheses are Conley spatial-HAC at 5 km with a Bartlett kernel. Columns 1 and 2 are located at each precinct's centroid; column 3 is located at the higher-exposure member's centroid. Column 2 absorbs county-by-measure fixed effects. Its slope is identified by 107,265 cells in 1,833 county–measure groups with within-group exposure variation; the observation count also includes groups with no within-group exposure variation. Column 3 contains 164,740 nonzero within-measure pair differences. Appendix Table A6 reports 10 and 25 km under both kernels for every column. Exposure is scaled by ballots cast on the same measure in the same election. * $p < .10$, ** $p < .05$, *** $p < .01$.

Figure A5: Illustration of the adjoining-precinct design. California's statewide Proposition 23 (2020) would have required dialysis clinics to maintain specified on-site physician coverage, report infection data, obtain state approval before closing or reducing services, and follow additional anti-discrimination rules. The left panel maps San Francisco precincts by mobilizing-firm workers per 100 official ballots cast. The precinct-cell analysis compares precincts voting on the same measure; the adjoining-precinct specification shown at right compares directly adjacent precincts, further reducing concerns about residential sorting.

Table A6: Conley Standard Errors at Alternative Bandwidths and Kernels

Column	Specification	Bartlett			Uniform		
		5 km	10 km	25 km	5 km	10 km	25 km
(1)	Precinct $\times$ measure, measure FE	0.472	0.627	0.826	0.653	0.815	1.031
(2)	Precinct $\times$ measure, county-by-measure FE	0.239	0.307	0.375	0.318	0.394	0.416
(3)	Adjacent pair, measure FE	0.104	0.106	0.108	0.104	0.111	0.111

Notes: Conley spatial heteroskedasticity- and autocorrelation-consistent standard errors for every column of Table A5, at three bandwidths under both kernels. Every reported specification includes measure fixed effects. County-by-measure fixed effects in column (2) restrict the levels comparison to precincts in the same county voting on the same measure. Reporting the full grid rather than one bandwidth makes each estimate's sensitivity to the assumed correlation range visible rather than a matter of choice. Point estimates are unchanged across columns; only the standard error varies.

Table A7: Spatial Block-Bootstrap Robustness

Specification	Estimate	10 km blocks		25 km blocks		Observations
		95% CI	<i>p</i>	95% CI	<i>p</i>	
Precinct cells, measure fixed effects	+4.126	[+3.025, +5.484]	< .001	[+2.617, +5.875]	.001	169,701
Precinct cells, county-by-measure fixed effects	+0.477	[-0.147, +1.179]	.158	[-0.288, +1.289]	.225	169,701
Adjacent pairs, measure fixed effects	+0.201	[+0.036, +0.454]	.055	[+0.022, +0.456]	.063	164,740

Notes: Each row resamples spatial grid blocks with replacement for 999 replications and refits its reported fixed effects in every draw. Rows correspond to columns (1)–(3), respectively, of Table A5.

C House Elections: Additional Analyses

C.1 Event Study: PAC Entries

Figure A6: Turnout around a firm's PAC entering the worker's own House district. Coefficients are from the de Chaisemartin and D'Haultfœuille (2023) switching estimator, restricted to entries, comparing within district $\times$ election and within worker, as in Column (1) of Table 9. The horizontal axis counts elections since entry, so 0 is the election in which the firm's PAC began funding the district. The points at -1 and -2 are the estimator's pre-entry placebos rather than normalizations. Bars are 95 percent confidence intervals with standard errors clustered on the Compustat parent.

C.2 Alternative Specification: Triple Difference

The main specification described in Equation 2 compares workers at firms with PACs within the same district. Limiting comparisons to workers at different firms within the same district accounts for race-specific factors and other local dynamics. However, another potential concern may be firm-wide confounding factors which are not limited to a district. To attempt to control for firm-level factors, I fit an additional triple-difference style specification, which identifies variation across both firms and districts within the same state. To make the specification estimable, I estimate the following equation

$$\tilde{y}_{fdt} = \beta D_{fdt} + \mu_{fd} + \lambda_{fst} + \varepsilon_{fdt}, \quad (\text{A4})$$

where

$$\tilde{y}_{fdt} = \bar{y}_{fdt} - \bar{y}_{-f,dt} \quad (\text{A5})$$

The outcome variable in Equation A4 is defined as the difference between $\bar{y}_{fdt}$, the turnout rate of firm f 's workers in district d at election t , and $\bar{y}_{-f,dt}$, the turnout rate of every other employer's workers in the same district and election. D_{fdt} is a treatment indicator defined as in Equation 2, μ_{fd} and λ_{fst} are once again firm $\times$ district and firm $\times$ state $\times$ election fixed effects.

As in Equation 2, the estimator is the de Chaisemartin and D'Haultfœuille (2023) switching estimator. In lieu of directly imposing λ_{fst} as a linear fixed effect, the model includes a nonparametric firm $\times$ state trend with cells weighted by their eligible workers.

Table A8: Main specification vs. within-state triple interaction

	<i>Dependent variable: turnout</i>	
	(1) Main specification	(2) Triple-interaction
Effect on turnout (pp)	0.57 (0.64)	0.07 (0.21)
Observations	7,075,505	167,324
Workers	2,108,563	8,750,483
House districts	376	376
Elections	5	5
States	49	49
Compustat parents	765	825
Switching units	461,285	5,886

Notes: All columns are estimated with the de Chaisemartin and D'Haultfœuille (2023) switching estimator and pool both entries and exits. Column (1) compares a firm's workers with other workers in the same district and election. Column (2) is estimated on firm $\times$ district $\times$ election cells, in which each firm's turnout rate is differenced against the other firms in the same district and election and compared only with the same firm's other districts in the same state. Standard errors are clustered at the Compustat parent company. * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$.

C.3 Senate Co-Funding and Incumbent Continuity

The main design may be confounded by firms which fund additional elections in a given state. While House elections are specific to a given district, PACs may also fund Senate candidates in statewide races. Another potential confounding factor may occur because of ordinary turnover when incumbent House candidates decline to run again, leading to an open race, which may have both different turnout and corporate funding dynamics. Table A9 restricts the estimation sample by (1) removing elections in which PACs funded a Senate race in the state and (2) restricting to district-elections in which the incumbent candidate stood for re-election.

Table A9: Robustness to potential confounding factors

	<i>Dependent variable: turnout</i>	
	(1) Excluding Senate co-funding	(2) Same incumbent only
Average total effect (pp)	0.23 (0.42)	0.67 (0.75)
Switching units	108,407	392,311
Compustat parents	718	761
Districts	376	376
Workers	1,221,062	2,044,753
Elections	5	5
States	49	49

Notes: Both columns are estimated with the de Chaisemartin and D'Haultfoeuille (2023) switching estimator and pool both entries and exits. Column (1) drops worker-elections whose Compustat parent also funds an on-ballot Senate candidate in the same state and cycle. Column (2) keeps only district-elections whose sitting member stood for re-election. Standard errors are clustered at the Compustat parent company. * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$.

C.4 Event Studies by Mechanism

Figure A7: Turnout around an entry into exposure, by the mechanism that produced it. Each panel is the switching estimator's event-study path for one column of Table 11, in the same order, restricted to entries.

C.5 Changes in Committee Assignments

Figure A8: House districts carrying a committee-appointment event, by cycle and type. A district is shaded when at least one delegation member newly joined, newly chaired, or left a NAICS-crosswalked committee that cycle. Lower 48 only.

D Case and Company Identification

This appendix describes how I identified the ballot question campaigns and contributing companies that comprise the sample, and how I linked those contributors to employer records in the employment-voter panel.

D.1 Campaign Universe and Case Selection

During a typical election cycle, over 100 state-level ballot questions appear across 30 or more states. I consider all state-level ballot questions from 2016 through 2024, supplemented by selected municipal ballot questions in cities where employment data coverage is available. Using campaign finance data from the National Institute on Money in Politics (now OpenSecrets), I identify ballot question committees that received corporate contributions (OpenSecrets 2026). From the resulting set, I select campaigns where one or more specific companies contributed to a ballot question committee.

D.2 Contributor-to-Employer Matching

A central challenge is linking the names of ballot measure contributors—as they appear in campaign finance records—to the corresponding employer entities in the Revelio Labs employment database (Revelio Labs 2024). Contributor names in campaign finance filings are not standardized: the same company may appear as “BLUE CROSS BLUE SHIELD OF MASSACHUSETTS,” “BLUE CROSS & BLUE SHIELD OF MA,” or “BCBS MASSACHUSETTS.” Meanwhile, Revelio’s employment records use corporate legal names that may differ from the contributor’s filing name (e.g., “Health Care Service Corporation” for Blue Cross Blue Shield of Illinois). The matching procedure must handle these discrepancies systematically.

Starting universe The campaign finance data contains 11,111 unique contributor names across all ballot measures in the sample states and years. Most of these are not employers—the universe includes unions, political action committees, advocacy organizations, political parties, religious organizations, and government entities alongside corporate contributors.

D.2.1 Entity Classification

I first classify each contributor into one of ten entity types using keyword pattern matching on the contributor name. The classifier checks the uppercased name against an ordered list of substring patterns:

- **Union:** AFL-CIO, SEIU, IBEW, Teamsters, Steelworkers, and 40+ additional union identifiers including “WORKERS LOCAL,” “TRADE COUNCIL,” and “BROTHERHOOD OF.”
- **PAC:** “POLITICAL ACTION,” “BALLOT MEASURE COMMITTEE,” “INDEPENDENT EXPENDITURE.”
- **Campaign committee:** “YES ON,” “NO ON,” “COMMITTEE TO ELECT,” “CITIZENS FOR,” “FRIENDS OF,” “CAMPAIGN.”
- **Advocacy:** “PLANNED PARENTHOOD,” “SIERRA CLUB,” “ACLU,” “CONSERVATION,” “CONSERVANCY,” “COALITION,” and 20+ advocacy organization identifiers.
- **Party:** “DEMOCRATIC PARTY,” “REPUBLICAN PARTY,” and state/national party variants.

- **Association:** “CHAMBER OF COMMERCE,” “ASSOCIATION OF REALTORS,” “FARM BUREAU,” “ASSOCIATION,” “FOUNDATION.”
- **Government:** “CITY OF,” “COUNTY OF,” “SCHOOL DISTRICT,” “DEPARTMENT OF.”
- **Religious:** “DIOCESE,” “CHURCH OF,” “MINISTRY.”

Contributors matching none of these patterns are classified as corporations. This keyword classification identifies 7,156 entities as potential corporate contributors.

Manual curation The keyword classifier is supplemented by a hand-curated exclusion list of 1,389 entities confirmed through manual review to be non-employers despite passing the keyword filter (e.g., “FWD.US,” a political advocacy organization; “Represent.Us,” a governance reform nonprofit). Most of that list names entities the keyword classifier had already placed outside the corporate pool; 1,036 of the entries remove an entity the classifier had called a corporation. A smaller set of manual overrides preserves entities that contain exclusion keywords but are genuine employers—for example, “Tillamook County Creamery Association” (a dairy cooperative with 77 employees) and “Kaiser Foundation Health Plan” (the operating entity of Kaiser Permanente).

After classification and exclusions, 6,120 corporate entities remain for matching.

D.2.2 Name Normalization

Before matching, I normalize both contributor names and employer names using the following rules, applied in order:

1. Convert to uppercase
2. Strip corporate suffixes: Inc, LLC, Corp, Corporation, Company, Co, Ltd, Limited, LP, LLP, PLC, Holdings, Group, International, Enterprises, Industries, The
3. Replace punctuation (except & and whitespace) with spaces
4. Collapse multiple spaces to a single space

This normalization maps “Procter & Gamble Co.” and “PROCTER & GAMBLE COMPANY” to the same key (“PROCTER & GAMBLE”), enabling exact matching across stylistic differences.

D.2.3 Employer Lookup Table

The target for matching is a lookup table of employer names and employee counts by state, extracted from the Revelio employment records. For each of the 52 state partitions in the employment data, I extract all unique company names, their Revelio company identifiers (RCIDs), employee counts (defined as the number of linked voters with active employment at that company), and primary NAICS industry classification. The extraction uses DuckDB for memory-efficient per-state queries over the parquet-formatted employment data. The resulting lookup contains approximately 20 million (company, state) entries.

D.2.4 Four-Tier Matching Cascade

Each contributor entity is matched against the employer lookup using a four-tier cascade. The tiers are applied in order; the first match found is accepted.

Tier 1: Manual aliases A hand-curated mapping of 321 contributor names to their corresponding employer names. These handle cases where automated matching is impossible: corporate renamings (“Fiat Chrysler” → “Stellantis”), DBA names (“Amerco” → “U-Haul”), abbreviations (“BNSF” → “BNSF Railway”), and subsidiary-to-parent mappings (“21st Century Fox America” → “Fox Corp.”). The alias file was built iteratively across five review rounds, starting from known difficult cases and expanding as automated tiers revealed gaps.

Tier 2: Exact normalized match The contributor’s normalized name is compared to all employer names in the lookup for each state where the contributor is active. If the normalized strings are identical, the match is accepted. This tier captures the majority of matches—companies whose filing name, after suffix stripping, is the same as their employer record name.

Tier 3: Fuzzy matching For short names (≤ 2 tokens after normalization), I apply *containment matching*: the contributor name is accepted as a match if it appears as a substring of an employer name with at least 10 employees. For example, “BASS PRO” matches “BASS PRO SHOPS OUTDOOR WORLD.” The employee threshold prevents false positives from small entities with coincidentally similar names.

For longer names (≥ 3 tokens), I use token-level Jaccard similarity:

$$J(A, B) = \frac{|A \cap B|}{|A \cup B|}$$

where A and B are the token sets of the contributor and employer names, respectively. To account for the discrete nature of Jaccard scores at different token counts, I apply graduated thresholds: $J \geq 0.67$ for 3-token names, $J \geq 0.60$ for 4+ token names. I use an inverted token index to efficiently identify candidate pairs sharing at least one token, avoiding exhaustive pairwise comparison.

Tier 4: Semantic similarity Remaining unmatched entities are embedded using OpenAI’s text-embedding-3-small model and matched via approximate nearest neighbor search using FAISS (Johnson et al. 2021). The employer lookup names are embedded and indexed using FAISS’s inner-product index on L2-normalized vectors, which computes cosine similarity. A match is accepted if the cosine similarity exceeds 0.85. This tier captures semantic matches that token-level methods miss—for example, “Progressive Casualty Insurance” matching “Progressive Corp.” Queries are restricted to states where the contributor is active to prevent cross-state false matches.

D.2.5 Post-Match Filtering

Three filters are applied after matching:

1. **Match blacklist.** A set of 248 known false-positive (contributor, employer) pairs is removed. These arise when an employer name is superficially similar to the contributor but refers to a different entity (e.g., “WSI US LLC,” a staffing company, matched to “Wynn Resorts”; “Horizon Pharma PLC,” an Irish biopharmaceutical company, matched to “Horizon Pharmacies, Inc.,” a Texas pharmacy chain). The blacklist was compiled through iterative manual review across five matching rounds and a comprehensive LLM-assisted validation of all matches (described below).
2. **Industry filter.** Matches where the employer’s NAICS classification indicates a non-employer entity are removed. The filter excludes all six-digit NAICS codes from 813000 through 813999 (NAICS 813xxx).

3. **Employer size threshold.** An employer enters the registry only where the employment data record at least 10 employees for it, assessed on the firm in the state its coverage row was computed in. A separate and larger threshold applies later, at the episode level rather than the firm level: an episode is estimated only if at least 50 employees of the mobilizing firms appear on that state's voter file at that election, pooled across every firm on that side of the measure. No filter at any stage removes an individual employer for having fewer than 50 linked voters.

D.2.6 Iterative Review

The matching pipeline was run five times, with manual review of all matches and high-contribution unmatched entities between rounds. Each review round produced three types of feedback: (a) new manual aliases for entities that should have matched, (b) additions to the entity exclusion list for contributors confirmed as non-employers, and (c) additions to the match blacklist for false-positive matches. The fourth round included a systematic investigation of all 1,743 unmatched entities with contributions of \$10,000 or more, using the employer lookup to identify candidate matches for manual verification.

D.2.7 LLM-Assisted Match Validation

After the iterative review, I conduct a comprehensive validation of all matched pairs using a large language model (Claude Opus 4.6, Anthropic). Each matched contributor–employer pair is evaluated for two properties: (a) whether the matched employer name plausibly refers to the same entity as the contributor name, considering subsidiaries, DBAs, and corporate renamings; and (b) the three most likely six-digit NAICS 2022 industry codes for the contributor company. The validation is performed by 12 parallel classification agents, each reviewing approximately 200 matches.

This validation identifies 157 false-positive matches, which are removed from the crosswalk. False positives are concentrated among Tier 3 fuzzy matches (39% invalid rate) rather than Tier 2 exact matches (1.9%).

The NAICS review reveals that Revelio's industry classifications are unreliable: in a random 50-row spot-check, 34% of Revelio-assigned NAICS codes were incorrect at the six-digit level. Common errors include holding-company codes assigned to operating subsidiaries (e.g., a commercial bank coded as "Corporate Managing Offices"), cannabis companies assigned to pharmaceutical manufacturing (no cannabis-specific NAICS code exists), tribal casino operations classified as amusement parks, and private law firms coded under government legal services. I replace Revelio's NAICS codes with the LLM's top classification for all companies in the crosswalk, applying manual overrides for known problem categories: cannabis companies are assigned 111998 ("All Other Miscellaneous Crop Farming"), tribal casino operations 713210 ("Casinos"), and tribal governments 921150 ("American Indian and Alaska Native Tribal Governments"). The LLM-assigned codes are mapped to the official Census Bureau NAICS 2022 classification.

D.3 Matching Results

The crosswalk used for estimation contains 2,424 contributor–employer pairs (one per contributor and state) covering 2,106 unique contributors, drawn from 6,120 candidate corporate entities, after validation, the post-match filters, and the exclusion of NAICS 813 membership and advocacy organizations. No embedding-similarity (tier 4) match survives the post-match filters.

The unmatched entities are predominantly small local businesses below the employment data provider's coverage threshold, entities with no U.S. workforce presence in the contributor's state, or misclassified

Table A10: Matching Results by Tier

Tier	Method	Matches
0	Manual employer-ID overrides	71
1	Manual aliases	298
2	Exact normalized	1,878
3	Fuzzy (Jaccard + containment)	177
4	Embedding similarity (FAISS, cosine ≥ 0.85)	0
Total		2,424

non-corporate entities that passed the keyword filter.

E Panel Construction

This appendix describes the data infrastructure underlying the analysis. The production backbone is a person-year pipeline that builds state-level November panels and enriches them with treatment metadata, partisanship measures, tenure, and spillover flags. For a subset of states where multiple relevant ballot dates fall in the same calendar year, a supplementary election-level pipeline resolves within-year timing ambiguity by constructing panels at the voter $\times$ election level.

E.1 Data Sources

Two primary datasets are linked to create the analysis panels.

Voter files Voter file data is publicly available from state and/or county officials but is difficult to collect. Like most scholars, I thus rely upon a commercial data vendor, L2 Data. L2 data are widely used in fields including management (Kagan et al. 2026; Frake et al. 2026; Raffiee et al. 2022) as well as other social sciences (Brown and Enos 2021; Chinoy and Koenen 2024). The L2 voter file contains administrative records for approximately 180 million registered voters across all 50 states and Washington, D.C. For each voter, the file includes a complete turnout history across all election types (general, primary, municipal), current and historical residential addresses, party registration where available, and demographic information (age, gender, and race/ethnicity).

Employment records Revelio Labs aggregates employment information from online professional profiles, covering over 100 million U.S. employment records. Each record includes the employer name, job title, start and end dates, seniority level, salary band, and NAICS industry classification. Revelio resolves employer names to a canonical company identifier and maps subsidiary relationships to ultimate parent companies.

Record linkage The two datasets share no common unique identifier. The Politics at Work project links them using a multi-stage approach. First, both datasets are partitioned by metropolitan statistical area (MSA) to reduce the scale of required comparisons while preserving plausible matches. Second, the project applies probabilistic record linkage following Enamorado et al. (2019), which weights multiple matching fields—name, gender, approximate age—by their discriminatory power. Third, it supplements these with machine learning approaches using large language model embeddings (Ornstein 2025) to capture name variations that string distance measures miss (e.g., transliterations, hyphenated surnames, nicknames). The resulting linked dataset covers approximately 40 million Americans with both employment histories and voter turnout records. More complete technical details of this merge, including replication code, are described in Frake et al. (2026) and Kagan et al. (2026).

E.2 Production Person-Year Pipeline

E.2.1 Step 1–2: Preprocessing

The linked employment-voter records are partitioned by state using the state code embedded in L2’s voter identifier (LALVOTERID). Separately, the raw L2 voter files are standardized: column names are harmonized across states, and election history columns are extracted for general, consolidated general, and local/municipal elections. Processed voter files are stored as state-level parquet files for efficient downstream access.

E.2.2 Step 3: Base November Panels

For each state, I construct a person-year panel covering November general elections from 2012 through 2024. The panel has one row per registered voter per election year.

Employment status is determined by creating snapshots as of November 1 of each year. A worker is considered employed at a given company if their employment record shows a start date before November 1 and no end date (or an end date after November 1). When a worker holds multiple active positions in the same snapshot, I retain a single primary job using a deterministic hierarchy: highest pos _seniority (Revelio’s 1–7 measure of job seniority, derived from job title and other fields), then highest pos _salary (Revelio’s estimated salary based upon geography, job titles, and other fields), then earliest pos _startdate, then lowest pos _pos _number. This rule is used for the production person-year panels so that each voter-year has at most one attached job record.

Turnout is derived from L2’s election history columns. A voter is coded as eligible if their registration date is on or before the election date and they have not been removed from the rolls. Among eligible voters, turnout is coded as 1 if the election history column indicates participation and 0 otherwise. I do not record voters as failing to turn out (i.e., a “0” value) for elections which occurred prior to their recorded registration date.

E.2.3 Treatment Assignment

Treatment is assigned by a flagging stage that reads the base panels of Step 3 directly, together with the firm–ballot-measure crosswalk, and writes a treatment-flagged panel for every state carrying an estimated episode. For each voter-year it records whether the voter was employed at a firm that contributed to a ballot-measure campaign in that state at that election, which measures that firm contributed to, and on which side. Firms are carried as company identifiers rather than as names, and each treated row stores parallel measure-identifier and stance arrays, so that a voter employed by a firm active on several measures is resolved per measure rather than collapsed to a single flag. The four-digit NAICS codes used as a matching stratum are inherited from each worker’s employment record in the base panel, for treated and control workers alike.

Treatment is evaluated *contemporaneously*: a voter is treated at a given election only if the employment snapshot for that election places them at a mobilizing firm, so workers who joined or left afterwards are not retroactively treated.

E.2.4 Enrichment: Partisanship Scores and Tenure

A separate enrichment chain adds company identifiers, voter-level treatment-group indicators, company partisanship scores, and employee tenure to the base panels. Company-level partisanship scores (VRscores) are merged from Revelio’s voter registration–based measures (Kagan et al. 2026). VRscores capture the partisan composition of each company’s workforce in a given year, ranging from 0 (entirely Democratic-registered) to 1 (entirely Republican-registered). Scores are loaded only for treatment years to avoid anachronistic measurement. Employee tenure is calculated as the duration of employment (in years) at the affected company as of the election date. I also merge same-MSA employer ideology from an external file by matching employer identifier, metropolitan statistical area, and year. The key Republican-share measure in that merge is pct _rep _imp, which captures the imputed two-party Republican share among workers in the same employer-by-MSA cell.

E.2.5 Local Election Panels

The Colorado and Washington local episodes are jurisdiction-restricted catalogs run against the ordinary statewide Colorado and Washington panels, subset to include only jurisdictions with local elections in my sample.

For the El Paso and Kansas City cases, a parallel pipeline constructs panels in person-election format (rather than person-year), with employment snapshots taken as of each local election date. This pipeline follows its own company-identifier and treatment-group steps, adapted for the municipal electoral calendar and geography-specific company lists.

E.3 Election-Level Pipeline for Multidate States

The person-year pipeline is sufficient for most states in the sample because the relevant ballot campaigns map cleanly to one November general-election observation per year. A subset of six states (AZ, CA, ME, MO, OH, OK), however, contains multiple relevant ballot dates in the same calendar year—for example, a May primary ballot measure and a November general-election measure in the same year. For these states, a year-level treatment indicator is too coarse: a voter can be untreated in one election and treated in another within the same calendar year.

The election-level pipeline addresses this by constructing panels at the voter $\times$ election level rather than voter $\times$ year. For each election family represented in the ballot-measure sample—even-year November general, odd-year November, primary, and residual other election types—the pipeline retains all available same-family elections back to approximately 2010, so that each treated election is anchored by multiple untreated periods for matching and trend assessment. Employment snapshots are taken as of each exact election date rather than November 1, and treatment is assigned using exact election dates and election families rather than panel_year.

The election-level pipeline produces treatment timing and matched estimation inputs for the affected states. The estimation code handles both panel grains through an election_key abstraction that maps to election_id for multidate states and panel_year for year-grain states, with sequence-based lag lookups replacing year arithmetic.

E.4 House Elections: L2 Snapshot Vintages

L2's standard data format includes a binary indicator of voters' turnout in historical elections. However, it does not indicate *where* a voter was registered to vote in past elections. To record not only turnout but also the specific House district in which a voter was eligible to vote at each election, I go back in time and find the closest point-in-time “snapshot” to each election date in each state. Figure A9 shows the snapshot used for each state and election. In most cases, especially for recent elections, I am able to use a “snapshot” within only several weeks of the election, ensuring that voters are accurately recorded.

Figure A9: L2 snapshot vintages against the election calendar.

F Ballot Measure Classification

F.1 Material Stake Classification

For each firm $\times$ measure pair, I assess the *material stake* for workers—i.e., the extent to which the ballot measure affects employees’ jobs, income, or working conditions.

This classification is based upon two independent LLM raters (Claude Sonnet 5 and gpt-5.6-terra, both at high reasoning effort). Each rating agent received information about the specific employer (employer name, NAICS code, corporate parent, and workforce size), a detailed description of the ballot measure (based upon the information available from Ballotpedia), and the stance the firm took (support or oppose). Based upon this information, each rater assigns both a 1–10 material stake score, as well as a corresponding classification into “High” (score 8–10), “Medium” (4–7), or “Low” (1–3), based upon the detailed classification guide provided in Table A11. Each rating agent also provides a written explanation for its score.

In cases where the two rating agents disagreed across categories (i.e., they do not agree whether the material stake is high, medium, or low), a third agent (Claude Opus 5) adjudicated between the two based upon the initial information provided as well as the written rationale provided by each rating agent. Of the 3,883 pairs, 3,006 were resolved by consensus and 873 required adjudication; the remaining 4, whose sector had been mis-coded, were re-rated with the sector omitted. Table A12 reports inter-rater agreement statistics; over 92% of firm–measure pairs are within 2 score points of one another.

Table A13 reports the final distribution after adjudication.

Table A11: Material Stake Coding Guide

Category	Score	Criterion	Anchoring example
High	10	Employees lose their jobs if it passes/fails. Existential.	Coal-mining company opposing a ban on coal power (miners lose their jobs)
	9	Major workforce restructuring likely (lay-offs, closures, pay cuts).	Taxi company opposing rideshare legalization (workforce made obsolete)
	8	Employees’ core job functions or working conditions change substantially.	Hospital system opposing Medicaid expansion repeal (staffing levels change)
Medium	7	Meaningful impact on job security or compensation, not existential.	Trucking company opposing emissions rules requiring fleet replacement (costly adaptation)
	6	Some employees affected (one division), others not.	Pharmaceutical company opposing a drug-pricing measure (some sales roles affected, R&D not)
	5	Plausible but indirect—the firm cares, employees might notice.	Technology company opposing a data-privacy measure (compliance costs, daily work unchanged)
	4	Firm has a financial interest but employees’ daily work is unaffected.	Bank opposing a financial transaction tax (revenue hit, tellers’ jobs same)
Low	3	Marginal—industry-adjacent, employees keep jobs and conditions regardless.	Insurer opposing tort reform (industry-adjacent, employees unaffected)
	2	Firm takes a position on a policy tangential to its sector.	Oil company supporting a school-voucher initiative
	1	No connection to the firm’s business or employees’ work. Purely political, reputational, or ideological.	Software company weighing in on an animal-welfare ballot measure

This coding guide was dispatched to two rating agents (Claude Sonnet 5 and gpt-5.6-terra), alongside descriptions of each company and ballot question.

Table A12: Inter-Rater Agreement: Material Stake Classification

Statistic	Value
Firm–measure pairs scored by both raters	3,883
Category agreement (High/Medium/Low)	3,010 (77.5%)
Cohen’s κ (three categories)	0.625
Pearson r (1–10 scores)	0.875
Within 1 point	2,825 (72.8%)
Within 2 points	3,575 (92.1%)
Disagreements adjudicated (Opus 5)	873

Table A13: Material Stake Distribution

Material Stake	Statewide	Local	Total	%
High (8–10)	394	7	401	10.3
Medium (4–7)	1,416	283	1,699	43.8
Low (1–3)	1,523	260	1,783	45.9
Total	3,333	550	3,883	100.0

Notes: Counts cover all coded firm $\times$ measure pairs, including pairs outside the estimation sample. Table 4 reports the distribution among statewide pairs in the estimation sample.

F.2 Policy Type Classification

I classify each ballot measure into one of ten policy type categories:

- **Industry Regulation:** measures that directly regulate a specific industry’s ability to operate, enter, or exit a market (e.g., cannabis legalization, gambling authorization)
- **Tax & Fiscal Policy:** measures that change tax rates, create or repeal taxes, or alter fiscal rules
- **Electoral & Governance:** measures affecting voting systems, redistricting, campaign finance, or government structure
- **Social & Civil Rights:** measures addressing abortion rights, gun control, criminal justice reform, or anti-discrimination
- **Labor & Employment:** measures on minimum wage, working conditions, paid leave, union rules, or occupational licensing
- **Education:** measures on school funding, vouchers, or teacher policy
- **Healthcare:** measures on health insurance, Medicaid, or drug pricing
- **Environment & Energy:** measures on emissions, clean energy mandates, or conservation
- **Housing & Land:** measures on rent control, property rights, or zoning
- **Other:** measures which do not fall into any of the above nine categories

This classification is based upon two independent LLM raters (Claude Sonnet 5 and gpt-5.6-terra, both at high reasoning effort). Each rating agent received a detailed description of the ballot measure (based upon the information available from Ballotpedia). Based upon this information, each rater assigned the ballot question into a policy type category.

In cases where the two rating agents disagreed across categories (i.e., they assign different policy types), a third agent (Claude Opus 5) adjudicated between the two based upon the initial information provided as well as the written rationale provided by each rating agent. Table A14 reports agreement between the two coding agents after the initial run (prior to resolving disagreements).

Table A14: Inter-Rater Agreement: Ballot Measure Policy Type Classification

Statistic	All	Statewide	Local
Measures classified	409	370	39
Rated by both raters	409	370	39
Raw agreement	389 (95.1%)	350 (94.6%)	39 (100.0%)
Cohen’s κ	0.945	0.939	1.000
Disagreements adjudicated	20		
Resolved to gpt-5.6-terra rater	16		
Resolved to Claude Sonnet 5 rater	4		

Table A15 reports the final policy type distribution after adjudication.

Table A15: Policy Type Distribution Across the Identified Statewide Measures

Policy Type	<i>N</i>	%
Industry Regulation	63	17.0
Electoral & Governance	56	15.1
Social & Civil Rights	55	14.9
Education	38	10.3
Tax & Fiscal Policy	38	10.3
Healthcare	35	9.5
Environment & Energy	34	9.2
Labor & Employment	24	6.5
Other	18	4.9
Housing & Land	9	2.4
Total	370	100.0

G Precinct Vote-Direction Construction

G.1 Precinct-Level Returns: Sources and Coverage

Precinct-level returns on ballot measures are harder to obtain than precinct-level returns on candidate races. The standardized academic collections—the MIT Election Data and Science Lab and the Voting and Election Science Team—publish precinct returns for *candidate* offices only. Neither publishes measure-level yes/no counts. Ballot-measure returns must therefore be obtained from each state’s own election authority, one state at a time, in whatever format that authority publishes. Although the turnout analysis spans 39 states, the vote-direction analysis is limited to seven states that publish precinct-by-precinct ballot question results as well as contemporaneous precinct shapefile boundaries. Table A16 lists the source used for each. Precinct boundaries are redrawn between cycles, so geometry is vintage-specific: each measure is matched to the shapefile for its own state and year, and precinct identifiers are scoped to that layer. In addition to data restrictions, I also limit the estimation to measures in which corporate funders were only active on one side of a ballot question, as it is not theoretically clear how to treat precincts with workers employed at multiple opposing firms.

Table A16: Precinct-Level Ballot-Measure Returns: Source by State

State	Authority	Granularity	Format
California	Statewide Database (SWDB)	Precinct (SRPREC)	CSV/DBF
Georgia	Secretary of State (historical)	Precinct	Precinct files
Massachusetts	Secretary of the Commonwealth	Precinct	Searchable database
North Carolina	State Board of Elections	Precinct	Flat file
North Dakota	Secretary of State	Precinct	CSV/Excel
Nevada	Secretary of State	Precinct	CSV/Excel
Oklahoma	State Election Board	Precinct	CSV/ASCII

Notes: Precinct *geometry* comes from a different source: the Voting and Election Science Team and the Redistricting Data Hub publish precinct shapefiles by state and vintage, and California is matched to the Statewide Database’s own SRPREC shapefile. Returns and geometry are joined by precinct identifier, then workers are placed into the resulting polygons.

H Ballot Measure Inventory

H.1 State Ballot Measures

Table A18 lists the 264 statewide ballot measures identified by the case-identification pipeline—every measure that drew a contribution from a linkable corporate donor—spanning 39 states and election years 2016–2024. For each measure, the table reports total contributions for and against, the number of matched employer–voter firms contributing to the measure, and the electoral outcome. Measure descriptions were researched via Ballotpedia; contribution data are from OpenSecrets.

Table A17: Statewide Ballot Measures by State and Election Year

State	2016	2017	2018	2019	2020	2021	2022	2023	2024	Total

Notes: Counts are unique statewide ballot measures in the estimation sample (measures producing at least one matched firm–ballot-measure episode). Odd years include off-cycle state elections.

Table A18: Ballot Measures in the Estimation Sample. Table includes the 264 measures for which at least one firm–ballot-measure episode produced matched treated and control workers. “Firms” counts corporate contributors matched to Revelio Labs employer records. Dollar totals include all non-individual contributors, which includes contributors who do not appear in the empirical sample.

State	Measure	Year	Description	\$ For	\$ Against	Firms	Out
AK	MEASURE 001	2016	Allow voter registration via permanent fund dividend application.	\$1.2M	—	6	P
AK	MEASURE 001	2018	Establish stricter salmon habitat protections and environmental permits.	\$1.7M	\$12.0M	29	F
AK	MEASURE 001	2020	Increase taxes on North Slope oil production significantly.	\$1.5M	\$18.8M	7	F
AK	MEASURE 002	2020	Replace primaries with open top-four system and ranked-choice voting.	\$13.7M	\$553K	4	P
AK	BALLOT MEASURE 001	2022	Call a convention to amend Alaska’s constitution.	\$62K	\$4.6M	2	F
AL	AMENDMENT 002	2016	Protect state park funds from reallocation to general budget.	\$62K	—	2	P
AL	AMENDMENT 001 (PRIMARY)	2020	Change state board of education from elected to appointed.	\$476K	—	10	F
AR	ISSUE 003	2016	Remove 5% cap on state-issued economic development bonds.	\$386K	\$29K	28	P
AR	ISSUE 006	2016	Legalize marijuana for medical use with state regulation.	\$1.7M	\$426K	5	P
AR	ISSUE 005	2018	Raise minimum wage from \$8.50 to \$11.00 over three years.	\$1.5M	\$155K	3	P
AR	ISSUE 001	2020	Make permanent the temporary 0.5% sales tax for transportation.	\$2.3M	\$3K	33	P
AR	ISSUE 002	2022	Require 60% voter approval for constitutional amendments.	\$1.3M	\$2.0M	1	F
AR	ISSUE 004	2022	Legalize recreational marijuana for adults age 21+.	\$14.1M	\$2.8M	8	F
AZ	PROPOSITION 205	2016	Legalize marijuana for adults 21+; establish regulation system.	\$6.5M	\$8.4M	38	F
AZ	Proposition 127	2018	Increase renewable energy standards to 50% by 2030	\$25.3M	\$41.1M	6	F
AZ	Proposition 207	2020	Legalize recreational marijuana for adults 21+	\$6.0M	\$1.1M	28	P
AZ	Proposition 208	2020	3.5% income tax on earnings above \$250,000 for education	\$22.8M	\$4.3M	13	P
AZ	Proposition 310	2022	0.1% sales tax for 20 years to fund fire districts	\$563K	—	2	F
AZ	Proposition 134	2024	Require signature distribution across 30 legislative districts for initiatives	\$584K	—	1	F
AZ	Proposition 138	2024	Allow restaurants to pay tipped workers 25% below minimum wage	\$25K	\$5.8M	1	F
AZ	Proposition 139	2024	Constitutional right to abortion before fetal viability	\$35.3M	\$1.3M	3	P
AZ	Proposition 140	2024	Open primary with all candidates competing; possible ranked-choice voting	\$16.9M	\$150K	4	F
AZ	Proposition 312	2024	Property tax refunds for non-enforcement of public nuisance laws	\$1.1M	—	12	P
CA	Proposition 51	2016	\$9 billion bond for K-12 and community college facilities	\$11.3M	—	53	P
CA	Proposition 52	2016	Extend hospital fees for Medi-Cal indefinitely without regular reauthorization	\$15.3M	\$11.1M	5	P
CA	Proposition 53	2016	Require voter approval for revenue bonds over \$2 billion	\$5.0M	\$21.3M	40	F
CA	Proposition 55	2016	Extend income tax increase on earnings over \$250K for 12 years	\$61.1M	\$2K	5	P
CA	Proposition 56	2016	Increase excise tax on cigarettes and tobacco products	\$38.5M	\$71.2M	20	P
CA	Proposition 57	2016	Parole consideration for nonviolent felons; judges decide juvenile prosecutions	\$24.5M	\$1.9M	14	P

Notes: "\$ For" and "\$ Against" report total contributions from all donors (not limited to firms in our sample) as recorded in OpenSecrets ballot measure contribution data. "Firms" is the number of companies in our matched employer-voter sample that contributed to this measure. Outcome codes: P = Passed, F = Failed, W = Withdrawn, P* = Passed but later overturned by court. Contribution data sourced from OpenSecrets (formerly FollowTheMoney). Measure descriptions researched via Ballotpedia.

H.2 Local Ballot Measures

Table A19 lists all 39 local ballot measure episodes included in the estimation sample, spanning Washington cities, counties and school districts, Colorado counties, El Paso TX, and Kansas City MO. The identification procedure follows three stages: (1) scraping campaign finance records, (2) verifying committee–ballot-question linkages, and (3) filtering to estimable episodes.

Campaign finance scraping Local ballot measure committees and their corporate contributors were identified from state campaign finance databases: Colorado’s TRACER system (Secretary of State bulk CSV downloads) and Washington’s PDC (Public Disclosure Commission Socrata API). In these two programmatic crosswalks, contributors were filtered to corporate entities, matched to Revelio Labs employment records, and required to have at least 10 linked employees and a contribution of at least \$1,000. Colorado applies the employee screen to the firm’s linked Colorado workforce; Washington applies it to the firm’s linked total across states. Industries classified as advocacy organizations (NAICS 813xxx) and campaign service vendors (advertising, PR, management consulting) were excluded. The El Paso and Kansas City cases use separately verified, hand-assembled company lists rather than the Colorado or Washington crosswalk rules.

Committee-to-ballot-question verification Unlike statewide ballot measures—where campaign finance records link directly to specific propositions—local campaign committees are often standing organizations that fundraise continuously across election cycles. A committee’s presence in a given year’s campaign finance records does not guarantee that a ballot question appeared on the ballot that year. To address this, each committee–year pair was independently verified against county election records, Ballotpedia, the Colorado Secretary of State’s election results archive, and local news coverage. For each entry, I confirmed: (a) the specific ballot question number, (b) a description of the measure, and (c) the election outcome. Committee–year pairs that could not be linked to a specific ballot question were excluded.

Episode construction After treated and control voters were restricted to the measure’s jurisdiction, Colorado and Washington candidate episodes with fewer than 20 treated voters were not sent to estimation. This preliminary catalog screen did not replace the estimator’s common pre-matching rule: local and statewide episodes alike required at least 50 treated voters with valid employment records before coarsened exact matching against employed controls whose employers do not mobilize on any measure in the state.

Table A19: Local Ballot Measure Episodes with Matched Corporate Contributors. Each row is one estimated episode (ballot measure campaign × stance). “Firms” counts corporate contributors matched to Revelio Labs employer records. “Treated” is the number of matched employees at contributing firms. Episodes require ≥50 treated voters; treated employees are retained when coarsened exact matching finds an employed control at a non-contributing firm in their cell.

Jurisdiction	Committee	Year	Stance	\$ Contrib	Firms	Treated
Adams, CO	SUPPORT ANYTHINK LIBRARIES	2018	Support	\$24K	7	125

H.3 Measures in the Precinct-Level Sample

The precinct-level analyses include a much smaller subset of the ballot questions used in the main analysis. Many states do not provide precinct-level results for ballot questions, which limits the sample; other states (Idaho, Maryland, Montana, and Virginia) have precinct results but I was unable to locate contemporaneous precinct geography maps (shapefiles) to assign voters to precincts. Additionally, it is not clear how to interpret precincts which include employees of different firms which mobilized in different directions on the same ballot question, so I exclude 12 ballot measures in which firms mobilized both in support of and against the measure. Table A20 lists the included measures, grouped by state.

Table A20: Ballot measures in the precinct vote-direction analysis. Precinct cells are precinct $\times$ measure observations as loaded (170,783 in total); the regressions use the 169,701 cells with a precinct centroid, dropping 1,082 cells (1,076 in California and 6 in Oklahoma).

State	Year	Measure	Corporate side	Precinct cells
CA	2020	Proposition 14	Support (yes)	17,572
